Ray:

I obviously did not witness your test so can only go by what you report back.
I dont understand why your signal is jumping around on the scope. Dont know how you are triggering the sweep? Should be a stable waveform display.

However with 30 mv input and 18 mv output that agrees with attenuation you should expect.

My test revealed that my filter was very close to 8830.7 khz Fc.

Any of these filter sweeps depend on the accuracy of the test gear you have. Ideally you would need a Sweep generator with accurate KW markers, or a Spectrum analyzer with a tracking generator, or a 2 port VNA (make some nice USB ones today). Absent these classic test gear then you have to use the old fashioned manual method you just employed. It has been done this way for years and plotted on graph paper (before PC and Excel!) .

However results are no better than the accuracy of your RF sig gen output frequency.

One other thing you could try is to key the rig with heater and SG switch on into dummy load and see if you now get out good RF output with your test 8830.30 injected at pin 4 in lieu the rigs carrier oscillator. You know with the 8830.7 applied by the CAR-2 board it doesnt produce any RF output in CW mode so if your filter Fc has shifted to 8830.3 you should see good RF output power by injecting that carrier oscillator frequency. Actual transmit RF output freq will be off a little but not of concern.

Other wise you can remove the filter and sweep in on bench terminated with the 600 ohm source resistor and the 600 load resistor.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

OK, I ran the same test you did. I connected the generator to pin 4 of the CAR-2 board and set the output for 300mV rms at 8830.70. I am using my scope and doing the math to convert from peak-peak to rms.

At D7 anode I increased the Car Pot level to 30mV rms. This occurred at about 2-1/2 position.

I then moved to the anode of D8 and swept from 8830.0 to 8840.0 At those two frequencies the signal is virtually non-existent. The peak occurs at 8830.30 and is approximately 18mV. It is hard to tell exactly because the signal is jumping around on my scope.

Either side of that frequency the signal drops off fast. For example, if I change the frequency to 8830.32 of 8830.28, the signal drops about 16mV.

I guess this pretty much confirms the filter is bad. I can still remove it from the board and sweep it with 600 ohm terminations but I don't think it will change anything.

Do you think at this point I should just get another CW filter and try it?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Ok dinner is over and grand kids gone and house quiet. I need a beer!

Here is what I did to sweep the CW filter:

1. Removed the Carrier Osc metal cover 2 screws and exposed CAR-2 board
2. Removed small screw in center of the board.
3. Gently wiggled and pulled on the 10 pin Molex connector and removed the board
4. Connected RF Sig Gen output cable to pins 4 and 3 . Hot lead to 4 and shield to 3 or ground
5. Powered rig on in CW mode. Heaters and SG switch off. Drive control at 1200. VFO at 14.2mhz, and CAR Level pot full CCW.
6. Connected RF millivolt meter to IF board TP-5 and adjusted RF Sig gen output for 300mv rms @ 8830.70.
7. Connected RF millivolt meter to Diode D7 at input to the CW filter and flipped rig to Send and increased Car Level Pot for approx 30 mv input. Car Pot level was at position "2" for 30 mv carrier level. .
8. Moved RF millivolt meter to Diode D8 and swept the RF sig gen from 8800 to 9000. Found peak in RF voltage at approx 15 mv at 8830.689.

So the Fc of my filter is very close to 8830.70 and the attenuation closely matches what is listed on the TX Level Diagram.

Suggest you do not use much more than 30mv rms or 85 mv p-p input at Diode D7.

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the

USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx

OK Ray been a real pleasure working with you. Clearly you are a step or two above average and have the test gear. I think I have only seen one bad filter in my approx 10 years of experience, but have seen several others report on this forum experiencing problems.

I dont know what other test you could perform. If you are confident that your DDS sig gen is producing a 8830.30 carrier then filter Fc has shifted.

Let me know the closure and we will see of someone else can run with the 40 meter dip issue. If not I will try to help you.

73s Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I guess the final test you suggested confirms the CW filter is bad. I will pull it out just to confirm.

My signal generator is DDS controlled and is adjustable in 1 Hz steps. I calibrated my Frequency Counter about 3 months ago against a OCXO. According to the counter, my DDS generator is 32 Hz high at 8.830000.

With the generator set to 8.830300 feeding pin 4 on the CAR-2 board, I am able to load the transmitter to full power in CW mode. At this frequency the TS-820S display is reading 14.199.6. Changing the frequency to 8.830400 or 8.830200 cuts the power in half. If I set the generator to 8.830700, I get the 60 ma resting plate current.

After I remove the filter and confirm it is bad, I will order a replacement.

Thanks for all your help with this. I still have to solve the issue of the dip on 40 meters not being correct. I will open a separate topic for this in a couple of days.

Ray AB7HE

Ray:

I obviously did not witness your test so can only go by what you report back.
I dont understand why your signal is jumping around on the scope. Dont know how you are triggering the sweep? Should be a stable waveform display.

However with 30 mv input and 18 mv output that agrees with attenuation you should expect.

My test revealed that my filter was very close to 8830.7 khz Fc.

Any of these filter sweeps depend on the accuracy of the test gear you have. Ideally you would need a Sweep generator with accurate KW markers, or a Spectrum analyzer with a

tracking generator, or a 2 port VNA (make some nice USB ones today). Absent these classic test gear then you have to use the old fashioned manual method you just employed. It has been done this way for years and plotted on graph paper (before PC and Excel!) .

However results are no better than the accuracy of your RF sig gen output frequency.

One other thing you could try is to key the rig with heater and SG switch on into dummy load and see if you now get out good RF output with your test 8830.30 injected at pin 4 in lieu the rigs carrier oscillator. You know with the 8830.7 applied by the CAR-2 board it doesnt produce any RF output in CW mode so if your filter Fc has shifted to 8830.3 you should see good RF output power by injecting that carrier oscillator frequency. Actual transmit RF output freq will be off a little but not of concern.

Other wise you can remove the filter and sweep in on bench terminated with the 600 ohm source resistor and the 600 load resistor.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

OK, I ran the same test you did. I connected the generator to pin 4 of the CAR-2 board and set the output for 300mV rms at 8830.70. I am using my scope and doing the math to convert from peak-peak to rms.

At D7 anode I increased the Car Pot level to 30mV rms. This occurred at about 2-1/2 position.

I then moved to the anode of D8 and swept from 8830.0 to 8840.0 At those two frequencies the signal is virtually non-existent. The peak occurs at 8830.30 and is approximately 18mV. It is hard to tell exactly because the signal is jumping around on my scope.

Either side of that frequency the signal drops off fast. For example, if I change the frequency to 8830.32 of 8830.28, the signal drops about 16mV.

I guess this pretty much confirms the filter is bad. I can still remove it from the board and sweep it with 600 ohm terminations but I don't think it will change anything.

Do you think at this point I should just get another CW filter and try it?

2. Removed small screw in center of the board.
3. Gently wiggled and pulled on the 10 pin Molex connector and removed the board
4. Connected RF Sig Gen output cable to pins 4 and 3 . Hot lead to 4 and shield to 3 or

ground
5. Powered rig on in CW mode. Heaters and SG switch off. Drive control at 1200. VFO at 14.2mhz, and CAR Level pot full CCW.
6. Connected RF millivolt meter to IF board TP-5 and adjusted RF Sig gen output for 300mv rms @ 8830.70.
7. Connected RF millivolt meter to Diode D7 at input to the CW filter and flipped rig to Send and increased Car Level Pot for approx 30 mv input. Car Pot level was at position "2" for 30 mv carrier level. .
8. Moved RF millivolt meter to Diode D8 and swept the RF sig gen from 8800 to 9000. Found peak in RF voltage at approx 15 mv at 8830.689.

So the Fc of my filter is very close to 8830.70 and the attenuation closely matches what is listed on the TX Level Diagram.

Suggest you do not use much more than 30mv rms or 85 mv p-p input at Diode D7.

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board

3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

45614. Kenwood Hybrids and a telex boom microphone

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-31 23:05:33 UTC
From: Brian Allen
Topic: 45614 Message: 45614

I dug out my old boom headset mic out of the attic to finally use. I believe it was used in aircraft, not sure about that, has an audio and a mic 1/4 stereo plug. I spent the afternoon converting it to the 4pin plug. I can hear audio and key the rig fine. There is no modulation speaking into the mic element. Before I start tearing into the unit, I was wanting to know if this type mic element will work with the hybrids. I pried the mic element enclosure open as much as I could. Its about the size of a nickel, with green magnet wire coming from the element. Should it work with the hybrids?

Thanks

Peter:

It appears you replaced Q1 dual gate mosfet RF amp. Not sure how you determined it was bad?

There is no reason to guess if your L41 step up xfmr is bad. Easy to test it in circuit.

The transformer provides approx 10dB gain which is approx 3X voltage step up ratio.

To test do this with rig powered off:

1. Apply 5mv rms or -33dBm @ 14.200 mhz at TP-1 on the RF board.

2. Locate deck S1-2 bandswitch wiper. If you follow the heavy black line on the schematic from the hot end of L41 to the junction of coupling cap C42 and the wiper of S1-2 you will find it very easy to connect a mini-grabber test lead at this point to measure the transformer output level. S1-2 is the first vertical red/brown pc board from the rigs front panel. Looking straight down on this board at approx the 1130 position you will see the bronze hair pin loop of S1-2. It has a small rectangular window cut in the loop where you can connect the test lead. Connect your RF millivolt meter or O-scope here.

With 5mv @14.2mhz injected at TP-1 you will measure approx 18 to 22 mv output at S1-2 if L41 is good. Any voltage step up ratio between 3 to 1 and 4 to 1 is good.

There are two other possiblities:
1. Bad L1 2.7uhy shunt choke in the BCB filter. This is easy to check after you remove L41 by injecting 5mv @2.0mhz at TP-1 and monitoring the RF voltage at the solder pad where the hot lead of L41 was previously connected. Slowly lower the RF sig gen frequency. As the BCB filter is a high pass filter should see the filter roll off at approx 1.6mhz.

2. Bad D2 internal TX protection shunt diode. This diode shunts rig produced RF to ground when the Driver tube is conducting to protect Q1 RF amp. It gets its turn on bias from IR drop across Driver tube cathode resistors divider. It has nothing to do with protecting the rig from accidental TX RF or nearby lightning as some believe. To test D2 do this:
A. Rig powered off
B. Inject 20 mv @14.2mhz at S1-2.
C. Monitor this signal level at Gate 1 of Q1 RF amp. Gate 1 is the lower left lead on the flat pack device. Can prod at the lead hole as it enters component side of the board with a floral pin or hat pin.
D. Connect negative lead from 3 vdc from bench supply or flashlite batteries to chassis ground. While monitoring the rf voltage at G1 tap the plus lead to resistor R35 or R41 near the Driver tube socket. Monitor the 20mv signal at Gate 1 and as you tap the dc voltage on and off the resistors a good D2 diode will be biased on and shunt a good portion of the 20mv signal to ground.

Accidental RF can hurt L41, Q1, D2 and L1. Never seen it hurt the 8.830 wave traps or the Molex connectors.

Approx values (out of circuit) are:

Primary
Resistance = 0.25 ohms
Inductance = 0.85uhy

Secondary
Resistance = 1.00 ohms
Inductance = 15.5uhy

You can also perform a excitation test out of circuit:
1. Inject 5mv @ 10.00mhz into the Primary winding. That is 10 mhz and not 1 mhz.
2. Connect RF millivolt meter or O-scope across the Secondary.
3. Adjust the slug tuned core for maximum RF output voltage. Should see approx 40mv with the core approx 1 turn outside the top of the shield can.

I would never remove L41 without testing in circuit to confirm it is bad. The above is suggested post rewind testing prior to re-installing in the rig.

Well after fixing the connectors I turned it on and heard static and little feint CW, Then shut it off for while and returned to the radio later turned it on and maybe a minute or less later the frequency display went very dim showing only the first couple 0's on the left if your looking at the display and then they fade to nothing the further right you go and the static faded away. Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

Dan,

  Simple question to start: Did any of the panel lights work prior to the loss of the digital readout and the loss of audio...and if so...do they still work?.

Also, try this simple check...is there a small round 9 pin plug or a piece of wire between pins 8 & 9 of the socket in the back of the rig where the remote VFO would plug into? If so, remove and re-install the plug several times...see what happens. Without this plug properly making contact or wire jumper being there...you lose power to the VFO...no digital readout and no signals heard.
Usually...it just won't work...versus just fades out. Try the above first

Hi Joe,

I've looked for similar notes without success.

What I did was adjust each to match the frequency specified for each crystals. Be careful because the the CW crystal X1 oscillates at two different frequencies depending on TX / RX. Look at the circuit and you'll see the CWR and CWT lines switch that crystal. I'm not a CW guy so I left that one well alone but I expect if you get that wrong you'll find it hard to net to other operators. It seems to me that you would probably net X1 for the right TX frequency and let CWR land where it may.

Maybe one of the other guys has a better idea regarding these adjustments.

Also, make sure the crystals start correctly once you adjust them. On one radio I couldn't get the LSB crystal to start reliably if tuned to the right frequency.

Regards

Lou

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

I forgot to mention there are at least two other ways to adjust LSB and USB carrier oscillators

Some would say that only way is the method described in the service manual by setting the roll off equally in TX mode.

There are two other ways if you lack stable accurate audio generator and wattmeter:.

1. Refer to the TS-830 Survival Guide Maintenance Section and you will find a method described that employs the Marker signal and S-meter. This is not as precise but works fine. Make sure to place AGC in Fast and need a lite touch on the VFO knob as you approach zero beat.

2, The other is to use your lap top and a diode noise bridge and audio spectrum analyzer software like Spectrogram. Lacking the diode noise bridge can just find a clear frequency. You take audio from the headphone jack and input into your line or mic input on your sound card. I use free version of Spectrogram. You can see a sample trace in the Files section. This is poor mans spectrum analyzer but fun to see your passband.

Remember how you adjust LSB and USB trimmers in Rx mode is how you will sound it TX mode. Some like a more bass presence and others like a more communications style audio.

Here's a simple exercise for those newbies wanting to learn.

Exercise description:
You have tuned up your TS-520 into a 50 ohm dummy load. The meter (meter switch set to IP), after completing the tune up steps, is indicating 200ma in CW mode.

Questions:
1. What is the DC voltage at pin 1 of final tubes V1 or V2?

2. What is the current flowing through each resistor, R3 and R4, in the Final Unit?

3. What is the power dissipated by each resistor, R3 and R4, in the Final Unit?

Please show your steps, in detail, how you arrived at each answer.

thanks for responses Joe and Gordon When I turned the radio back on after following both of your suggestion and the display and the static came back. Then a few seconds later the both the relays on the bottom started clicking randomly and I could see the mechanisms inside moving and the frequency display starting jumping around. Then the relays stop clicking the freq display responded to the knob but there was no static or response on the af gain knob. Then the relays started clicking again static came back af gain response came back and the display would sometimes respond to the main tuning knob and would also jump around. It looked like the jumping frequency was in unison with the relays clicking. I turned it off after this.

Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

The answers are simple if you ASSUME some things.

1. the correct answer for 1 is less than 1 volt (very slightly, but none the less - less than1v). IF you assume that the 3.3k resistor is still part of the circuit, and it is because you stated it was reading the CATHODE current. If the meter is not in the circuit AND we assume the resistors are really 10 ohms each AND we assume there is little resistance in the wires and connection, then we can assume the voltage is nomally 1 volt.
2. Here you must ASSUME again. IF the resistors are exactly 10 ohams AND we assume they are exctly equal (which in reality we know is not true), AND we assume the meter is correct, we hap-hazaradly apply Kircoffs current law and ASSUME the current splits equally. The theoretical answer would be 100mA. THe real answer is unknown.
3. IF you assume equal resistor values, AND assume the meter is accurate (which it is NOT), again applying Kircoffs law, we get P=I^2 R or one tenth of one watt per resistor.

What you learn by this exercise is theory and actual real-world measurements are two different things.

Gee, and I didn't even graduate highschool!

Cathode meter shunt resistors are 5% tolerance, the series meter multiplier is 5%, the ua meter movement internal resistance is nominal and varies slightly from meter to meter, VTVMs, VOMs, and DMMs have a % accuracy, test leads have resistance, what is the ambient temperature? and on and on and on in the real world.

I dont think any of the above has anything to do with the fundamentals that this exercise is trying to address.

I once told a young man that nothing was impossible and he smugly replied "try lighting a bar of soap under water". He missed the message and I hope he had a nice life flipping burgers. Not that that is not an honorable profession!

Maybe I am missing something?

ok thank you all for the help and i will execute all the information over the weekend and the let you know the results after this.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Approx values (out of circuit) are:

Primary
Resistance = 0.25 ohms
Inductance = 0.85uhy

Secondary
Resistance = 1.00 ohms
Inductance = 15.5uhy

You can also perform a excitation test out of circuit:
1. Inject 5mv @ 10.00mhz into the Primary winding. That is 10 mhz and not 1 mhz.
2. Connect RF millivolt meter or O-scope across the Secondary.
3. Adjust the slug tuned core for maximum RF output voltage. Should see approx 40mv with the core approx 1 turn outside the top of the shield can.

I would never remove L41 without testing in circuit to confirm it is bad. The above is suggested post rewind testing prior to re-installing in the rig.

Ok here goes nothing. Now I have a few things that are confusing me right away. Im not sure whether the 50 ohm dummy load's was added to the total resistance or not, I did it both ways. I used the schematic from the 820 final, I am hoping the resistors that are labeled R3 R4 are the same as the 520 because in one of your videos you said the Cathode and IP meter circuit (and im not sure if the meter adds a load)were the same. I also wasn't sure if should add in the resistance from the IP meter, I did it both ways as well. The first answer I do not my believe is affected by my confusion and I got 1 volt after getting the total resistance from the two 10 ohm resistors R2 R3 and with the 200 milliamps I applied ohms law E = IR or 1 = .2 x 5. the second question for R3 I got .1 amps after I applied I = E/R or .1 = 1/10 (here I wasn't sure if used just the 10 ohms from R3 or the total resistance from R2 and R3 or 5 ohms for 5 ohms its .2), for R4 at 3300 ohms the current would be .000303 amps at 3350ohms (if you add the 50 ohm dummy load) current would be .000299 If you add the 800 ohms from the ip meter to the resistance the current at 4100 ohms would be .000243 amps and for 4150 ohms (again w/ dummy load if needed) the current would be .000240 amps. I got those value by applying I = E/R. The power drop for R3 I got .1 watts (using 10ohms for 5 ohms or the total resistance of R2 and R3 it would be .05). for R4 for 303 micro amps the power drop is .000303 watts, for 299 micro amps the power drop is .000299 watts for 243 micro amps the power drop is .000242 watts and for 240 micro amps the power drop would be .000239. I got these by multiplying resistance value at each resistor to the squared value of the current at each resistor. or P = I^2 x R

This is my first attempt and I wasn't sure on a lot of it but this was a great exercise and all but 1 or 2 of the books have don't have any exercises after chapters so this is especially helpful and the ones that do im not ready to read yet. so thanks again mike your really helping me out. And I usually need to get things wrong a few time before they start clicking, so all you gurus, take it eeeaasyy on me ok.

Daniel

They are all fair enough questions. A sensible answer would show at least 4 things-
1. A basic knowledge of Ohms law.
2. A basic understanding of voltage and current.
3. An idea of real world component values and tolerances.
4. Understanding that seriously dangerous voltages exist in tube transmitters.

Now, I really feel that I must say this.
What on Earth is someone who cannot give a reasonable answer to the questions posed doing trying to service or repair an older piece of gear like a Kenwood hybrid?
If you want to be an "appliance operator" then do so, but accept the fact that you are NOT going to be able to repair (or fully understand) the workings of your equipment and the hobby is going to be more expensive for you.
It seems like learning to swim by jumping into the deep end!
So might I suggest that if a bit of study or effort is too much trouble then this might not be the right hobby for you. In fact most hobbies require some and that to me is what makes them worthwhile.

Its probably an electret mic. Especially if it is VERY small and light.
In which case it will need a supply voltage trough about a 4k7 Ohm
resistor with the audio taken off the mic side thru a capacitor of 0.1
uF or more. I use one with my Kenwood 820S quite successfully but iI use
an external 9 volt battery controlled by a PTT switch (I don't like VOX).

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an
expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP. In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay
contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You
can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

Daniel,

On the TS-520 schematic, R3 & R4 are the cathode resistors in the final amp section. The test questions are asking for the DC currents, voltages, and power related to the resistors. You can ignore the 50 dummy load for your calculations as it is in the output circuit and is coupled through a capacitor (no DC current flows through the capacitor and to the antenna) and for other reasons.

Technically the IP (plate current) meter is reading cathode current. If all is going well the cathode current is a close approximation of the plate current.

You can ignore the load of the meter. Why? The meter is connected to the cathode resistors through a 3.3K resistor. The meter also has a resistance, but lets assume it is zero. So, as you recognized, the current will divide between each 10 ohm resistor and the 3.3K resistor, inversely proportional to the resistance. How much of the cathode current goes through the cathode resistors? The two 10 ohm resistors in parallel form 5 ohms. It will be:

3300/ (3300+5) = 0.999847 times the cathode current. This number will be even larger if we include the resistance of the meter in our calculations.

As you can see, ignoring the load of the meter circuit introduces an error of less than 0.1%

Now, go back and try the questions again using only the two 10 ohm cathode resistors and the 200mA plate current.

73,

Bill, WA6NEQ

Subject: [TS-520_820_530_830] RE: Question for newbies

Ok here goes nothing. Now I have a few things that are confusing me right away. Im not sure whether the 50 ohm dummy load's was added to the total resistance or not, I did it both ways. I used the schematic from the 820 final, I am hoping the resistors that are labeled R3 R4 are the same as the 520 because in one of your videos you said the Cathode and IP meter circuit (and im not sure if the meter adds a load)were the same. I also wasn't sure if should add in the resistance from the IP meter, I did it both ways as well. The first answer I do not my believe is affected by my confusion and I got 1 volt after getting the total resistance from the two 10 ohm resistors R2 R3 and with the 200 milliamps I applied ohms law E = IR or 1 = .2 x 5. the second question for R3 I got .1 amps after I applied I = E/R or .1 = 1/10 (here I wasn't sure if used just the 10 ohms from

R3 or the total resistance from R2 and R3 or 5 ohms for 5 ohms its .2),
for R4 at 3300 ohms the current would be .000303 amps at 3350ohms (if you add the 50 ohm dummy load) current would be .000299 If you add the 800 ohms from the ip meter to the resistance the current at 4100 ohms would be .000243 amps and for 4150 ohms (again w/ dummy load if needed) the current would be .000240 amps. I got those value by applying I = E/R. The power drop for R3 I got .1 watts (using 10ohms for 5 ohms or the total resistance of R2 and R3 it would be .05). for R4 for 303 micro amps the power drop is .000303 watts, for 299 micro amps the power drop is .000299 watts for 243 micro amps the power drop is .000242 watts and for 240 micro amps the power drop would be .000239. I got these by multiplying resistance value at each resistor to the squared value of the current at each resistor. or P = I^2 x R

This is my first attempt and I wasn't sure on a lot of it but this was a great exercise and all but 1 o! r 2 of the books have don't have any exercises after chapters so this is especially helpful and the ones that do im not ready to read yet. so thanks again mike your really helping me out. And I usually need to get things wrong a few time before they start clicking, so all you gurus, take it eeeaasyy on me ok.

Daniel

Joe,

All I could find was to connect RF VTVM to "OUT" of the carrier board....function switch to "VFO" and adjust T-1 for maximum

I think that you can check the frequencies directly on the board...if I remember there is an X-ray view with the terminals marked and shows the crystal frequencies in the service manual I looked at(it's a 520S) They should be:

USB = 3396.5kHz

LSB = 3393.5

CW(R) = 3394.3

CW(T) = 3395.0

You should be able to adjust the frequencies if they are off by using TC-1, 2 & 3.

I could be wrong...it's been quite a while since a looked at a 520(s)

Any time you set the Carrier Osc frequencies for LSB and USB modes to the frequencies listed in the manual you are just at the starting point. The CW Carrier Osc is only one you would set and leave at the listed frequency.

There are two requirements 1. Correct output level set first and then 2. Bring the carrier oscillators to the Xtal IF Filter Fc as you cannot change the filter response and cannot assume it is spot on.

The service manuals all provide the procedure. Some call it adjusting the Carrier Point. Some call it adjusting the SSB Frequency Response. Typically you would go to the Balanced Mod trimmer cap and trimmer pot and adjust the LSB and USB Carrier Balance first. Then perform the LSB/USB Carrier Osc adjustment procedure.

After completing these adjustments it is a good idea to go back and re-check the Carrier Suppression.

I have previously described 3 ways to do this:
1. Watt meter and audio generator (preferred method described in SM)
2. Marker and S-meter (see TS830 Survival Guide maintenance section)
3. Audio spectrum analyzer software. (Have described it numerous times)

Daniel,

On the TS-520 schematic, R3 & R4 are the cathode resistors in the final amp section. The test questions are asking for the DC currents, voltages, and power related to the resistors. You can ignore the 50 dummy load for your calculations as it is in the output circuit and is coupled through a capacitor (no DC current flows through the capacitor and to the antenna) and for other reasons.

Technically the IP (plate current) meter is reading cathode current. If all is going well the cathode current is a close approximation of the plate current.

You can ignore the load of the meter. Why? The meter is connected to the cathode resistors through a 3.3K resistor. The meter also has a resistance, but lets assume it is zero. So, as you recognized, the current will divide between each 10 ohm resistor and the 3.3K resistor, inversely proportional to the resistance. How much of the cathode current goes through the cathode resistors? The two 10 ohm resistors in parallel form 5 ohms. It will be:

3300/ (3300+5) = 0.999847 times the cathode current. This number will be even larger if we include the resistance of the meter in our calculations.

As you can see, ignoring the load of the meter circuit introduces an error of less than 0.1%

Now, go back and try the questions again using only the two 10 ohm cathode resistors and the 200mA plate current.

Ok lets try this again with much friendlier values this time and thanks for the clarification from William.

1) E = .2amps(5ohms) = 1 volt

2) I = 1/10 = .1 amps for both R3 and R4

3) P = (.1)(.1)(10) = .1 watts of power dissipation from R3 and R4

Dan,

Great job!!!

If you are interested in reading/studying, may I recommend the following:

1. Basic Radio Course by John T. Frye.

There's an eBay seller selling the late 40's edition of this book. I highly recommend it.

2. ARRL Handbook - late 60's and earlier editions

3. Radio Handbook by William Orr W6SAI (Bill's an SK)

Bill Orr's book is a similar book as the ARRL Handbook. You can find this book quite often on eBay. I found my excellent condition hardback copy on eBay for $19 free shipping.

You can also use my videos at

www.n6wk.com/w5rkl/

Click on the appropriate link/folder then select the video you would like to watch.

I might also recommend you purchasing a breadboard. The breadboard can have it's own built in power supply or be powered by an external supply. I found my breadboard with built in supply at

http://www.allelectronics.com/index.php

You can power the breadboard from lantern batteries.

Don't make the mistake of ignoring having to learning the basics as many hams have done. Learn and have a solid foundation on the basics before you attempt to move into more advanced and complex areas of electronics. While today's electronics are mostly solid state there are still plenty of uses for vacuum tubes. Learn vacuum tube theory, how a simple diode, triode, tetrode, and pentode vacuum tube works. It's not as difficult as you may think.

Again, congratulations on answering all the question correctly in the simple exercise.

http://www.n6wk.com/w5rkl/ http://www.n6wk.com/w5rkl/ are some videos Mike w5rkl did that helped me. If you doo a google search for "Orr radio pdf" there a good book on radio and electronics. Well I just started on this one but Mike also has some suggested readings on that link and this was one of them I found for free in PDF form.
http://www.tubebooks.org/technical_books_online.htm
http://www.tubebooks.org/technical_books_online.htm I think the Orr Radio Handbook can be found at this link along with several other books concerning radios and electronics many if not all in PDF all for free. Hope this helps. Based on all my confusion on answering the questions I need to read lots more still. Though this stuff is pretty basic I tend to get a little nervous at test time.

Daniel

Now, go back and try the questions again using only the two 10 ohm cathode resistors and the 200mA plate current.

Subject: [TS-520_820_530_830] RE: Question for newbies

Ok here goes nothing. Now I have a few things that are confusing me right away. Im not sure whether the 50 ohm dummy load's was added to the total resistance or not, I did it both ways. I used the schematic from the 820 final, I am hoping the resistors that are labeled R3 R4 are the same as the 520 because in one of your videos you said the Cathode and IP meter circuit (and im not sure if the meter adds a load)were the same. I also wasn't sure if should add in the resistance from the IP meter, I did it both ways as well. The first answer I do not my believe is affected by my confusion and I got 1 volt after getting the total resistance from the two 10 ohm resistors R2 R3 and with the 200 milliamps I applied ohms law E = IR or 1 = .2 x 5. the second question for R3 I got .1 amps after I applied I = E/R or .1 = 1/10 (here I wasn't sure if used just the 10 ohms from R3 or the total resistance from R2 and R3 or 5 ohms for 5 ohms its .2), for R4 at 3300 ohms the current would be .000303 amps at 3350ohms (if you add the 50 ohm dummy load) current would be .000299 If you add the 800 ohms from the ip meter to the resistance the current at 4100 ohms would be .000243 amps and for 4150 ohms (again w/ dummy load if needed) the current would be .000240 amps. I got those value by applying I = E/R. The power drop for R3 I got .1 watts (using 10ohms for 5 ohms or the total resistance of R2 and R3 it would be .05). for R4 for 303 micro amps the power drop is .000303 watts, for 299 micro amps the power drop is .000299 watts for 243 micro amps the power drop is .000242 watts and for 240 micro amps the power drop would be .000239. I got these by multiplying resistance value at each resistor to the squared value of the current at each resistor. or P = I^2 x R

This is my first attempt and I wasn't sure on a lot of it but this was a great exercise and all but 1 o! r 2 of the books have don't have any exercises after chapters so this is especially helpful and the ones that do im not ready to read yet. so thanks again mike your really helping me out. And I usually need to get things wrong a few time before they start clicking, so all you gurus, take it eeeaasyy on me ok.

Daniel

Here's a simple exercise for those newbies wanting to learn.

Exercise description:
You have tuned up your TS-520 into a 50 ohm dummy load. The meter (meter switch set to IP), after completing the tune up steps, is indicating 200ma in CW mode.

Questions:
1. What is the DC voltage at pin 1 of final tubes V1 or V2?

2. What is the current flowing through each resistor, R3 and R4, in the Final Unit?

3. What is the power dissipated by each resistor, R3 and R4, in the Final Unit?

Please show your steps, in detail, how you arrived at each answer.

Hey joe I cleaned the relays (the plugs were a little blackened but inside was shiny and clean) and no change, once I turned it back on they started clicking randomly again with the frequency jumping around on the display each time they clicked. Im not even sure what the relays do so Ive got some reading to do before ill try anything. Im not ready to do any real work on this beast yet. So far Ive only been able to locate one of the relays on the schematic and there's a lot there I don't understand, including tracing the circuits in line with the relay. And the only description in the service manual is for the relay unit and its a brief description that gives me a little on what to start reading about. Any information would be helpful.

Daniel

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP.
In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Terry K9TW

Hi Dan, Mike, Terry, and all on the list. I hope this finds you well,

If you are interested in books, textbooks, old, & out-of-print books, there is a web seller/broker called www.abebooks.com. It appears they act as a clearing-house for many booksellers/dealers. They give info & ratings for the sellers. They do have 4 copies of Frye's book at this time rangong from $30.20 shipped(pretty good) to $115.00 shipped(This happens when a seller deals with the collector's market where the need to have over-rides all common sense.) We found the site while we were putting our 4 children through college and it helped defray a lot of textbook cost. The sellers give a pretty fair appraisal of the condition of the copy so you've got an idea what you're getting. I searched on ARRL handbooks and found many pages of league handbooks of all varieties. There was even a 1948 course in fundamentals by George Grammer with experiments & exercises basd on The Handbook for 1948 for around 46.00 shipped. (It was on page 10 of my
search for arrl handbooks) The inventory at any time changes based on what becomes available so it pays to visit every once-in-a-while. Some of the newer handbooks are quite cheap(no collectors value) and will save you some dough. Don't forget the Goodwill, Salvation Army Stores and garage sales as possible sources either. You never know when some good samaritan is going to clean out Grama & Grampas's attic. I collect and love books but I'm too cheap (& broke) to pay collector prices but abe has served me well. The detailed book listing will give you pub dates and conditon info for each book so you aren't buying a "pig in a poke".

In any event I thought I'd toss the info out. Hope it helps.

Vy 73,
mjsyn (Mike)

You'd like $300 but what would take take with careful packaging (I received a 520 a few weeks ago wrapped in a single laye of small-bubble bubble wrap and a light sprinkling of newspaper pages in the rest of the box --it did NOT survive the trip) and shipping to 07626 in NJ? And, of course, do you take Paypal?

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Hey joe I cleaned the relays (the plugs were a little blackened but inside was shiny and clean) and no change, once I turned it back on they started clicking randomly again with the frequency jumping around on the display each time they clicked. Im not even sure what the relays do so Ive got some reading to do before ill try anything. Im not ready to do any real work on this beast yet. So far Ive only been able to locate one of the relays on the schematic and there's a lot there I don't understand, including tracing the circuits in line with the relay. And the only description in the service manual is for the relay unit and its a brief description that gives me a little on what to start reading about. Any information would be helpful.

Daniel

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP.
In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

They USED to be a clearing-house, and fiercely independent, one small book shop competing with and helping out the other.

Until the owners sold out to Amazon, and now they are a wholly-owned subsidiary with only profit maximization for the parent company as a goal. A lot of the smaller sellers pulled out, two in my little neck of the woods alone, rather than pay the Danegeld which Amazon wanted.

Add in the Amazon policy towards what us computer geeks know as "DRM" (Digital Rights Management, or that insane piece of 'copyright' legislation we've been screwed with by the idiots in D.C.) and it adds up to why I stopped using ANY of the Amazon affiliated stores a few years ago.

And there are more of them than you might believe.

Yes, it likely takes me a good, oh, five more minutes, to find a non-Amazon-sourced item, but I can spare the five minutes to support SMALL business owners. I only wish more people would have done the same, and spared the extra five minutes for me when I was a small businessman, and before Wally-World (another "I don't go there. Period." place) spent the better part of three years losing money on every piece-of-junk computer they sold in this area, solely to put me out of business.

Yes, I'm a little bitter about it, even twenty-odd years later. But I live just fine, and have made acquaintance with some fine small business-people, all without supporting more of these corporate behemoths than I absolutely have to.

Hi Guys,

It is highly recommended that if you are going to buy and this is purely my opinion and what I do when sending or receiving radios.

Double box, use plenty of bubble wrap and foam peanuts and pay the extra for insurance.

Recently I bought a TL922 for restoration, the old fellow double boxed and even went to the extent of putting padded masionite board on all six sides, it cost me $A306.00 to ship it. Biggest mistake made was the words "handle with care, fragile and this way up". Needless to say only damage was two broken feet tabs, they can't be welded or fixed, but have a better way of repairing. When I reported back to courier service was told - see you in small claims court we're not paying!

The old guy rang me a few days later and he had the same thing when he bought the amp years before.

Morale of the story, don't be cheap when boxing, difference between arriving dead or alive

> Ok here goes nothing. Now I have a few things that are confusing me right away. Im not sure whether the 50 ohm dummy load's was added to the total resistance or not, I did it both ways. I used the schematic from the 820 final, I am hoping the resistors that are labeled R3 R4 are the same as the 520 because in one of your videos you said the Cathode and IP meter circuit (and im not sure if the meter adds a load)were the same. I also wasn't sure if should add in the resistance from the IP meter, I did it both ways as well. The first answer I do not my believe is affected by my confusion and I got 1 volt after getting the total resistance from the two 10 ohm resistors R2 R3 and with the 200 milliamps I applied ohms law E = IR or 1 = .2 x 5. the second question for R3 I got .1 amps after I applied I = E/R or .1 = 1/10 (here I wasn't sure if used just the 10 ohms from R3 or the total resistance from R2 and R3 or 5 ohms for 5 ohms its .2), for R4 at 3300 ohms the current would be .000303 amps at 3350ohms (if you add the 50 ohm dummy load) current would be .000299 If you add the 800 ohms from the ip meter to the resistance the current at 4100 ohms would be .000243 amps and for 4150 ohms (again w/ dummy load if needed) the current would be .000240 amps. I got those value by applying I = E/R. The power drop for R3 I got .1 watts (using 10ohms for 5 ohms or the total resistance of R2 and R3 it would be .05). for R4 for 303 micro amps the power drop is .000303 watts, for 299 micro amps the power drop is .000299 watts for 243 micro amps the power drop is .000242 watts and for 240 micro amps the power drop would be .000239. I got these by multiplying resistance value at each resistor to the squared value of the current at each resistor. or P = I^2 x R
>
> This is my first attempt and I wasn't sure on a lot of it but this was a great exercise and all but 1 o! r 2 of the books have don't have any exercises after chapters so this is especially helpful and the ones that do im not ready to read yet. so thanks again mike your really helping me out. And I usually need to get things wrong a few time before they start clicking, so all you gurus, take it eeeaasyy on me ok.

We used the Floyd texts. About the same, actually. I think I have both somewhere in the basement on the shelves. Should be next to the "Basic Blacksmithing and Metal Work" texts.

Hi Guys,

It is highly recommended that if you are going to buy and this is purely my opinion and what I do when sending or receiving radios.

Double box, use plenty of bubble wrap and foam peanuts and pay the extra for insurance.

Recently I bought a TL922 for restoration, the old fellow double boxed and even went to the extent of putting padded masionite board on all six sides, it cost me $A306.00 to ship it. Biggest mistake made was the words "handle with care, fragile and this way up". Needless to say only damage was two broken feet tabs, they can't be welded or fixed, but have a better way of repairing. When I reported back to courier service was told - see you in small claims court we're not paying!

The old guy rang me a few days later and he had the same thing when he bought the amp years before.

Morale of the story, don't be cheap when boxing, difference between arriving dead or alive

You'd like $300 but what would take take with careful packaging (I received a 520 a few weeks ago wrapped in a single laye of small-bubble bubble wrap and a light sprinkling of newspaper pages in the rest of the box --it did NOT survive the trip) and shipping to 07626 in NJ? And, of course, do you take Paypal?

Learn Ohm's Law, and how to apply it. That's a good 95% of all you'll ever need to know about electronics there, and the rest you can crib from data sheets and the RSGB handbook ;-)

Yes Grob and Schrader are classic texts on my bookshelf, but I still strongly recommend the late 60s to mid 70s ARRL Handbooks. The reason is that it is not good enough to study basic electronics and not build upon that toward how it applies to our KW rigs. The ultimate goal is to understand how a Receiver works and how a Transmitter works. The Handbook is designed to do that in a logical sequence.

If you look at the chapters of the ARRL handbook or RSGB handbook you will see that they start with Basic Electronics, DC/AC, components, power supplies, amplifiers, oscillators, mixers, power amplification.....receiver building blocks, and transmitter building blocks.

You can sub the ARRL handbook basic electronic chapters with Grob and other texts, but why not use a text book that is oriented to Radio Electronics.

If you want to start very basic go to Ebay and order ARRL's Understanding Amateur Radio, which is a condensed version of the Handbook. In about 50 pages it takes you from Ohms Law to Transistors and then proceeds to explain how a receiver works and what is mixing, bfo, agc, resonance, tank circuit, Q, etc. Then the same with a basic transmitter.

I was there when this text came out and the old timers all lamented at that time what has happened to this hobby when you need to have a watered down Handbook for these newbies! It was very controversial.

Grob and Schrader are great, but for under $10 on Ebay can get Understanding Amateur Radio and after reading it and you want more in depth coverage can go back to Grob.

As they say IMO

Oh by the way I do have a 2009 ARRL Handbook and it makes a great door stop!

Daniel,

On the TS-520 schematic, R3 & R4 are the cathode resistors in the final amp section. The test questions are asking for the DC currents, voltages, and power related to the resistors. You can ignore the 50 dummy load for your calculations as it is in the output circuit and is coupled through a capacitor (no DC current flows through the capacitor and to the antenna) and for other reasons.

Technically the IP (plate current) meter is reading cathode current. If all is going well the cathode current is a close approximation of the plate current.

You can ignore the load of the meter. Why? The meter is connected to the cathode resistors through a 3.3K resistor. The meter also has a resistance, but lets assume it is zero. So, as you recognized, the current will divide between each 10 ohm resistor and the 3.3K resistor, inversely proportional to the resistance. How much of the cathode current goes through the cathode resistors? The two 10 ohm resistors in parallel form 5 ohms. It will be:

3300/ (3300+5) = 0.999847 times the cathode current. This number will be even larger if we include the resistance of the meter in our calculations.

As you can see, ignoring the load of the meter circuit introduces an error of less than 0.1%

Now, go back and try the questions again using only the two 10 ohm cathode resistors and the 200mA plate current.

Bill, WA6NEQ

Subject: [TS-520_820_530_830] RE: Question for newbies

Ok here goes nothing. Now I have a few things that are confusing me right away. Im not sure whether the 50 ohm dummy load's was added to the total resistance or not, I did it both ways. I used the schematic from the 820 final, I am hoping the resistors that are labeled R3 R4 are the same as the 520 because in one of your videos you said the Cathode and IP meter circuit (and im not sure if the meter adds a load)were the same. I also wasn't sure if should add in the resistance from the IP meter, I did it both ways as well. The first answer I do not my believe is affected by my confusion and I got 1 volt after getting the total resistance from the two 10 ohm resistors R2 R3 and with the 200 milliamps I applied

ohms law E = IR or 1 = .2 x 5. the second question for R3 I got .1 amps after I applied I = E/R or .1 = 1/10 (here I wasn't sure if used just the 10 ohms from R3 or the total resistance from R2 and R3 or 5 ohms for 5 ohms its .2), for R4 at 3300 ohms the current would be .000303 amps at 3350ohms (if you add the 50 ohm dummy load) current would be .000299 If you add the 800 ohms from the ip meter to the resistance the current at 4100 ohms would be .000243 amps and for 4150 ohms (again w/ dummy load if needed) the current would be .000240 amps. I got those value by applying I = E/R. The power drop for R3 I got .1 watts (using 10ohms for 5 ohms or the total resistance of R2 and R3 it would be .05). for R4 for 303 micro amps the power drop is .000303 watts, for 299 micro amps the power drop is .000299 watts for 243 micro amps the power drop is .000242 watts and for 240 micro amps the power drop would be .000239. I got these by multiplying resistance value at each resistor to the squared value of the current at each resistor. or P = I^2 x R

This is my first attempt and I wasn't sure on a lot of it but this was a great exercise and all but 1 o! r 2 of the books have don't have any exercises after chapters so this is especially helpful and the ones that do im not ready to read yet. so thanks again mike your really helping me out. And I usually need to get things wrong a few time before they start clicking, so all you gurus, take it eeeaasyy on me ok.

Hello All
I am stuck with a strange problem.
I had signed with the yahoo group for many years and receive regularly posting from the kenwood hybrids,
TS 430/440/ Fox tango etc. A few days ago i wanted to check some in fo in the files section of the TS 520,530,830
etc group and i was surprised to receive a message telling me my account has been de activated ,because of not accessing the group for a long time.I was advised to creat a new account.This is where all the problem lies.
The yahoo computer in all its wisdom asked me for my mobile phone number,and when this was given , I was told that that number
was not a valid mobile phone number.I re ceive calls and sms on the same mobile phone number almost every day from UK,HB9.France , DL etc with no problem. The problem is why Yahoo does not recognise a number from Mauritius thouh I have given the country code etc. I have asked my son 3B8GL to create an account and he gets the same problem of non recognition of the mobile number.
Can some knowledgeable guru make any head or tail about this problem.
Thanks and Regards
Jacky 3B8CF

Dan

Do the relays key normally when you flip to Send?

The relays are keyed by transistor switch Q9 on FIX board. Q9 is biased on two ways :
1. By grounding the SS terminal with the Send switch or the mic PTT switch
2. Audio input in VOX mode

So to be have random cycling of the relays Q9 has to be being turned on and off. The more typical failure is for Q9 to have failed short and rig stays keyed. This usually is caused by a failure of flyback diode D17 and resulting high counter emf during relay coil de-energizing damages Q9. It does not appear that your Q9 is hurt but something is biasing it on and off.

Suggest you consider buying a FIX-VOX board from Bob Mansker. Board swap out would be easier than talking you through troubleshooting the relay keying circuit on the FIX board.

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hey joe I cleaned the relays (the plugs were a little blackened but inside was shiny and clean) and no change, once I turned it back on they started clicking randomly again with the frequency jumping around on the display each time they clicked. Im not even sure what the relays do so Ive got some reading to do before ill try anything. Im not ready to do any real work on this beast yet. So far Ive only been able to locate one of the relays on the schematic and there's a lot there I don't understand, including tracing the circuits in line with the relay. And the only description in the service manual is for the relay unit and its a brief description that gives me a little on what to start reading about. Any information would be helpful.

Daniel

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP.
In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as

stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

> Well after fixing the connectors I turned it on and heard static and little feint CW, Then shut it off for while and returned to the radio later turned it on and maybe a minute or less later the frequency display went very dim showing only the first couple 0's on the left if your looking at the display and then they fade to nothing the further right you go and the static faded away. Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

Terry

The relays stop cycling when I switch it to send, I agree a board switch would be easier. I've been tracing everything attached to the Relay board on the schematic and then tracing those to circuits on the various other boards, which has been fun, but I still wasn't sure how it worked. I've been searching for info on the relays and their circuits but haven't been able to find much(I may be missing something in the manuals). Any information you or anyone could give or point me to would be very helpful. Thanks for everyone's help already. I can feel I am getting close (with yalls help of course) to getting this beauty talking to me.

Daniel

Do the relays key normally when you flip to Send?

The relays are keyed by transistor switch Q9 on FIX board. Q9 is biased on two ways :
1. By grounding the SS terminal with the Send switch or the mic PTT switch
2. Audio input in VOX mode

So to be have random cycling of the relays Q9 has to be being turned on and off. The more typical failure is for Q9 to have failed short and rig stays keyed. This usually is caused by a failure of flyback diode D17 and resulting high counter emf during relay coil de-energizing damages Q9. It does not appear that your Q9 is hurt but something is biasing it on and off.

Suggest you consider buying a FIX-VOX board from Bob Mansker. Board swap out would be easier than talking you through troubleshooting the relay keying circuit on the FIX board.

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Terry K9TW

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP. In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig

around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

Topic: 45672 Message: 45672

Greetings Group!

It looks like November has just started and already has several "new member requests." I guess the word is getting out that this is the place to go for SUPERIOR information, SUPERIOR friendship and, SUPERIOR help, regarding these fine Kenwood hybrids. Let's keep it that way!

For newly "approved" members, the rules are simple: sign your posts/questions with your "first" or "given name" and, your call sign...if any. "Screen Names" are ONLY acceptable in the "header" of your e-mail address. Be respectful of other members of this group...as stated on numerous prior occasions: opinions vary....diagnostic interpretations may vary...this does NOT mean you need to get "pissy" about differing "opinions," IF you have a problem with what another group member said/stated....contact that member DIRECTLY......and try and work it out..IF, for some reason...you can not..contact either me...Joe-wb7uqu (Group Co-owner), Gordon-n6wk(moderator) or Mike-w5rkl(moderator)...and we will attempt to "work it out for you." Continual violation of these simple rules will be cause to have your posts "moderated," or worst case...BANNED.

For "new" members of this group: We do not know your skill or, knowledge level, we do not know what "diagnostic equipment" you have...so PLEASE indicate the prior and latter. For me...at times, I'm still trying to fully understand some "squiggly lines" on my o'scope...and sometimes...looking at a schematic...trying to figure..out WTF!

To the "moderators:" I have taken 1 "new" member off "moderate" as he has shown the ability to follow the rules and, "works and plays well with others." I don't really know why I'm so stuck on that phrase....but that's what I always saw on my elementary school report cards.

So Group....' nuf said...let's all work and play well with others and not run with scissors...we now return to our regular programming......

73 Joe
WB7UQU
Group Co-owner and I'm sure, "other names."

45674. Kenwood Hybrid Net Update (November 3, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-03 19:12:38 UTC
From: <mgilger@...>
Topic: 45674 Message: 45674

The Saturday net we had 18 check-in with excellent band conditions. There were 3 new check ins, K8AEC, WA2JID, and VA3ACI. We had the following number of radios checking in.

2 running TS-520(x)
2 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
1 running R599A / T599A

I was running my TS-940s.

The Sunday's 20 meter net had 13 stations checking in under good band conditions. Out of those, there was:

4 running TS-520(x)
1 running TS-530(x)
2 running TS-820(x)
1 running TS-830S

I was running my TS-820s.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940's, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 – Oct. 2012 Saturday total 754 check-ins, Sunday total 563 check-ins

November 2012, Saturday's, net total = 47, Sundays total = 20
December 2012, Saturday's, net total = 74, Sunday's total = 70
January 2013, Saturday's, net total = 93, Sunday's total = 87
February 2013, Saturday's net total = 103, Sundays total = 87
March 2013, Saturday's, net total = 112, Sunday's total =39

April 2013, Saturday’s net total = 52, Sunday’s total = 29
May 2013, Saturday’s net total = 45, Sunday’s total = 50
June 2013, Saturday’s net total = 30, Sunday’s total = 27
July 2013, Saturday’s net total = 63, Sunday’s total = 41
August 2013, Saturday’s net total = 82, Sunday’s total = 50
September 2013, Saturday’s net total = 66, Sunday’s total = 54
October 2013, Saturday’s net total = 61, Sunday’s total = 55
November 2013, Saturday’s net total = 18, Sunday’s total = 13 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

If you had the test gear we could look at SS termnal and TO terminals for starters. I am inclined to suspect problem on TO line. You could jumper from base to the emitter of Q7 and see if relays stop cycling. Have to make sure you are on the correct leads. Probably not good thing for you to attempt at this point.

You wont find any KW circuit descriptions for relay keying that I am aware of. They assume certain base knowledge level. .

As for understanding how the relay circuit works for starters you could Google on using transistors to key relays. Or start with how to use a transistor as a switch. On Google will find common transistor config tutorials including switches You will learn what it means by driving the transistor into Saturation and Cut-off regions.

Also with time you could look at the circuit and recognize the flyback or back emf diode and understand what happens in a relay coil (an inductor) when the Dc current flow is suddenly interrupted. This is basic inductor fundamentals.

You can also Google on Schmitt Trigger and Relay "Snap Circuits" to understand what Q7 and Q8 are doing and why this config is used and important for proper relay keying.

With time you will start to recognize certain configurations when you see them (like a Balanced Mod or Product Detector) on the KW hybrid schematics. I can do it pretty well and it only took me 50 years! Yet I still am a student of the KW hybrid design. Learn new things all the time. .

Dont get discouraged. If you have the interest and aptitude you will be able to figure out how these circuits work and you can look at the other hybrid models and see basically same relay keying circuits repeated with slight variations.

I try to give a little fundamentals with each of my answers. Some like that and some do not. Much easier to just give the answer, but what would anyone learn?

Right now for test gear all I have is a signal generator/ tracer combo, and a VTVM. But I agree most of your suggestions arnt for me to attempt, I will be saving and bringing them to the ham club when I finally get out to one and let the experienced people help.

And after you had mentioned a flyback diode in a previous reply I went to look it up and couldn't figure out where the inductance they were talking about was coming from so you've all ready answered one question. With a lot of this stuff I don't what to google to get a good return, so this answer will give me plenty to read. Ill post more questions as they arise.

Thank you so much

Daniel

If you had the test gear we could look at SS termnal and TO terminals for starters. I am inclined to suspect problem on TO line. You could jumper from base to the emitter of Q7 and see if relays stop cycling. Have to make sure you are on the correct leads. Probably not good thing for you to attempt at this point.

You wont find any KW circuit descriptions for relay keying that I am aware of. They assume certain base knowledge level. .

As for understanding how the relay circuit works for starters you could Google on using transistors to key relays. Or start with how to use a transistor as a switch. On Google will find common transistor config tutorials including switches You will learn what it means by driving the transistor into Saturation and Cut-off regions.

Also with time you could look at the circuit and recognize the flyback or back emf diode and understand what happens in a relay coil (an inductor) when the Dc current flow is suddenly interrupted. This is basic inductor fundamentals.

You can also Google on Schmitt Trigger and Relay "Snap Circuits" to understand what Q7 and Q8 are doing and why this config is used and important for proper relay keying.

With time you will start to recognize certain configurations when you see them (like a Balanced Mod or Product Detector) on the KW hybrid schematics. I can do it pretty well and it only took me 50 years! Yet I still am a student of the KW hybrid design. Learn new things all the time. .

Dont get discouraged. If you have the interest and aptitude you will be able to figure out how these circuits work and you can look at the other hybrid models and see basically same relay keying circuits repeated with slight variations.

I try to give a little fundamentals with each of my answers. Some like that and some do not. Much easier to just give the answer, but what would anyone learn?

The relays stop cycling when I switch it to send, I agree a board switch would be easier. I've been tracing everything attached to the Relay board on the schematic and then tracing those to circuits on the various other boards, which has been fun, but I still wasn't sure how it worked. I've been searching for info on the relays and their circuits but haven't been able to find much(I may be missing something in the manuals). Any information you or anyone could give or point me to would be very helpful. Thanks for everyone's help already. I can feel I am getting close (with yalls help of course) to getting this beauty talking to me.

Do the relays key normally when you flip to Send?

The relays are keyed by transistor switch Q9 on FIX board. Q9 is biased on two ways :
1. By grounding the SS terminal with the Send switch or the mic PTT switch
2. Audio input in VOX mode

So to be have random cycling of the relays Q9 has to be being turned on and off. The more typical failure is for Q9 to have failed short and rig stays keyed. This usually is caused by a failure of flyback diode D17 and resulting high counter emf during relay coil de-energizing damages Q9. It does not appear that your Q9 is hurt but something is biasing it on and off.

Suggest you consider buying a FIX-VOX board from Bob Mansker. Board swap out would be easier than talking you through troubleshooting the relay keying circuit on the FIX board.

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Terry K9TW

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP. In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig

around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

A LOT LESS.

I have college degrees in electronics and engineering and I STILL don't grok some of (who am I kidding, a LOT OF!) the design of these radios.

Terry's tutorials and troubleshooting treatises keep me humble, for one thing.

Keep doing them, PLEASE.

I don't know about anyone else, but I'm learning from them.

I've got them all archived from the day I joined the list, truth be told, and search there before I ask anything. So far it has worked well, I got that 520SE running, into a dummy load so far while I build a ladder line and dipole. But it is running, and I have Terry and Gordon and Mike and some others to thank for it. It will stay running well, mostly due to these tutorials others are getting, too.

Dan:

Yes need to start with basics of what happens when a dc current flows thru a coil of wire (the relay closing coil) and what happens when a collapsing magnetic field cuts the turns of a coil of wire to understand what counter emf is and how the diode protects the transistor switch.

Here is a brief description of how a Schmitt Trigger functions as a "Snap Action" circuit for positive relay keying. A little broken english but is the principle of how Q7 and Q8 works.

Might want to save in your notes for future reference.

Wes

We could use the help from graduate RF engineers who worked in the field. With 3000 plus members have to be some 1964 EE grads who grew up with tubes and went on to work in RF design. We dont have to design or reverse engineer the rigs but sure would help if we had more detailed circuit descriptions.

I have had some formal EE education but changed my major (calculus got the best of me) to Business and only worked briefly in the industry as a Communications Tech for a large electric utility before being moved into management roles never to touch tools or test gear again.

So what I tell you about how these KW hybrids work is what I have had to scratch and dig to learn. There are circuits that I have yet to figure out how they work. Typically your understanding comes from where you have problems. It always amazes me when you have a problem with these circuits how you can pull the string all the way back to Grob or ARRL Handbook if you really have the inclination.

I appreciate the fact that you have found that my daily dose of fundamentals that I like to include in my responses has been helpful to you.

Terry K9TW

A LOT LESS.

I have college degrees in electronics and engineering and I STILL don't grok some of (who am I kidding, a LOT OF!) the design of these radios.

Terry's tutorials and troubleshooting treatises keep me humble, for one thing.

Keep doing them, PLEASE.

I don't know about anyone else, but I'm learning from them.

I've got them all archived from the day I joined the list, truth be told, and search there before I ask anything. So far it has worked well, I got that 520SE running, into a dummy load so far while I build a ladder line and dipole. But it is running, and I have Terry and Gordon and Mike and some others to thank for it. It will stay running well, mostly due to these tutorials others are getting, too.

45682. Whackamole & Pin2 on PLL connector 8

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

As I try to resurrect this TS830S that someone butchered, I find it is like playing whackamole. I finally got the receiver to work quite well & the S meter now responds with appropriate readings (all bad connections of some sort). But then I find the CAL won't produce a signal. I trace that down to a bad ground, probably caused by me when I had the front panel off. But as I trace the orange CAL switch wire back to pin 3 on connector 8 on the bottom side of the PLL board, I notice that #2 wire is completely missing in that connector. The pin hole inside the connector is empty & there is no loose wire anywhere nearby. The pin is named RLR on the schematic. Any comments? Late engineering change? This radio is wearing me out. Thanx - Bob

I am a member of a lot of groups and I think Joe is not making false statements. The quality of messages on this board is very good.

In a lot of instances, some guys are even taking great pains to help some pretty rookie repair guys who do seem to have got over their heads which is really nice to see. A real Elmer spirit.

Bob,

I am a bit confused on your description of "on the bottom side of the PLL board."

  I just happen to have an 830S on the bench...open...here's what Connector 8 on the PLL board(X50-1680-00)(this is on the component side..as viewed):

  Connector 8:

Pin 1: BLUE wire
2: EMPTY
3: ORANGE
4: BROWN
5: YELLOW
6: GREY
7: WHITE
8: RED
9: VIOLET

  The "destinations" of the different wires are listed in the "service manual" on Pg 62...under
"PLL Unit"

Subject: RE: RE: RE: RE: RE: RE: Re: RE: Re: Re: Re: Re: [TS-520_820_530_830] RE: question about IF board connections

Dan:

Yes need to start with basics of what happens when a dc current flows thru a coil of wire (the relay closing coil) and what happens when a collapsing magnetic field cuts the turns of a coil of wire to understand what counter emf is and how the diode protects the transistor switch.

Here is a brief description of how a Schmitt Trigger functions as a "Snap Action" circuit for positive relay keying. A little broken english but is the principle of how Q7 and Q8 works.

Might want to save in your notes for future reference.

http://www.electroschematics.com/5784/snap-action-relay/

Right now for test gear all I have is a signal generator/ tracer combo, and a VTVM. But I agree most of your suggestions arnt for me to attempt, I will be saving and bringing them to the ham club when I finally get out to one and let the experienced people help.

And after you had mentioned a flyback diode in a previous reply I went to look it up and couldn't figure out where the inductance they were talking about was coming from so you've all ready answered one question. With a lot of this stuff I don't what to google to get a good return, so this answer will give me plenty to read. Ill post more questions as they arise.

Thank you so much

Daniel

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

If you had the test gear we could look at SS termnal and TO terminals for starters. I am inclined to suspect problem on TO line. You could jumper from base to the emitter of Q7 and see if relays stop cycling. Have to make sure you are on the correct leads. Probably not good thing for you to attempt at this point.

You wont find any KW circuit descriptions for relay keying that I am aware of. They assume certain base knowledge level. .

As for understanding how the relay circuit works for starters you could Google on using transistors to key relays. Or start with how to use a transistor as a switch. On Google will find common transistor config tutorials including switches You will learn what it means by driving the transistor into Saturation and Cut-off regions.

Also with time you could look at the circuit and recognize the flyback or back emf diode and understand what happens in a relay coil (an inductor) when the Dc current flow is suddenly interrupted. This is basic inductor fundamentals.

You can also Google on Schmitt Trigger and Relay "Snap Circuits" to understand what Q7 and Q8 are doing and why this config is used and important for proper relay keying.

With time you will start to recognize certain configurations when you see them (like a Balanced Mod or Product Detector) on the KW hybrid schematics. I can do it pretty well and it only took me 50 years! Yet I still am a student of the KW hybrid design. Learn new things all the time. .

Dont get discouraged. If you have the interest and aptitude you will be able to figure out how these circuits work and you can look at the other hybrid models and see basically same relay keying circuits repeated with slight variations.

I try to give a little fundamentals with each of my answers. Some like that and some do not. Much easier to just give the answer, but what would anyone learn?

The relays stop cycling when I switch it to send, I agree a board switch would be easier. I've been tracing everything attached to the Relay board on the schematic and then tracing those to circuits on the various other boards, which has been fun, but I still wasn't sure how it worked. I've been searching for info on the relays and their circuits but haven't been able to find much(I may be missing something in the manuals). Any information you or anyone could give or point me to would be very helpful. Thanks for everyone's help already. I can feel I am getting close (with yalls help of course) to getting this beauty talking to me.

Daniel

Dan

Do the relays key normally when you flip to Send?

The relays are keyed by transistor switch Q9 on FIX board. Q9 is biased on two ways :

1. By grounding the SS terminal with the Send switch or the mic PTT switch

2. Audio input in VOX mode

So to be have random cycling of the relays Q9 has to be being turned on and off. The more typical failure is for Q9 to have failed short and rig stays keyed. This usually is caused by a failure of flyback diode D17 and resulting high counter emf during relay coil de-energizing damages Q9. It does not appear that your Q9 is hurt but something is biasing it on and off.

Suggest you consider buying a FIX-VOX board from Bob Mansker. Board swap out would be easier than talking you through troubleshooting the relay keying circuit on the FIX board.

Dan:

I should not be sticking my nose in Joe and Gordons thread but just one suggestion. Did someone already mention to make sure the Vox paddle switch is turned off or down to Manual position?

If VOX is on and VOX gain pot (under the VFO knob) is turned up can cause your relays to cycle.

Dan,

Gordon does have a point...but...the 820S will receive just fine even though the digital display is disconnected....it's called the 820. The 820 started out with NO digital display...but it could be added "after market." There was such a demand..that they came out with the "S" model..which came from the factory with the digital display and associated components already installed.

Since it appears that you may have purchased this rig from a "well know auction site," you do not know the whole history and/or care of this rig. So with that in mind...let's start simple...as you stated that your knowledge/skill level is very basic...that's ok...I'm NOT an expert either...but I do have some experience with this rig....so...we do not know right know what exact fault(s) that is/are causing your problem. The rigs can and will suffer from NOT being used!

Get some good tuner/contact cleaner...I use DEOXIT...others have their favorite...and a can of "canned air," aka... "air duster" The DEOXIT can be found at Radio Shack...the "canned air" at Walmart or decent computer/office supply stores and some "stiff card stock." Just about any good, clean,stiff, unlined paper will do.

With rig UNPLUGGED from power...remove top and bottom covers....turn rig bottom UP.
In the middle you will see a couple of round capacitors with a RELAY next to them...remove the relay...it un-plugs. The plastic cover can be removed with the use of a small screwdriver. Just be careful. You will see numerous contacts...saturate the card stock with some contact cleaner...insert the paper between the relay contacts...and move the paper back and forth numerous times...you will notice..possibly some "black stuff" on the paper...that's good...your getting rid of it...you will have to use your fingers to manually operate the relay armature to get them all clean...use different clean parts of the paper...blow off with "canned air." Clean the relay socket too.. reinstall relay cover...reinstall relay.

The other relay is at the rear corner, by the final amplifier board, under the metal shield. remove shield, remove relay, remove relay cover...clean and blow off contacts as stated above. Put it all back together...Check for operation.

A note of CAUTION: you will be working around some HIGH VOLTAGE AREAS!(900VDC) Check with voltmeter for HIGH VOLTAGE at the capacitors just behind the "relay board" or the "800" terminal on the HV UNIT. The voltage will bleed off over time..usually 10 minutes or less...but ALWAYS CHECK ANYWAY! You can find them on the picture of the underside of the rig in the "operation manual." The functions of these relays is a topic for another time..but they control a bunch of stuff.

If you do not feel comfortable with this...that's OK too..maybe you can find some help.

Thanks to my "yahoo mail" crashing...it only took me 4 hours to write this.....

thanks for responses Joe and Gordon When I turned the radio back on after following both of your suggestion and the display and the static came back. Then a few seconds later the both the relays on the bottom started clicking randomly and I could see the mechanisms inside moving and the frequency display starting jumping around. Then the relays stop clicking the freq display responded to the knob but there was no static or response on the af gain knob. Then the relays started clicking again static came back af gain response came back and the display would sometimes respond to the main tuning knob and would also jump around. It looked like the jumping frequency was in unison with the relays clicking. I turned it off after this.

> Well after fixing the connectors I turned it on and heard static and little feint CW, Then shut it off for while and returned to the radio later turned it on and maybe a minute or less later the frequency display went very dim showing only the first couple 0's on the left if your looking at the display and then they fade to nothing the further right you go and the static faded away. Im not smart enough to try any actual fixes but if you or anyone could point to the right direction so I read up on the circuits and go over schematics and other related sections in the manuals that would really help. thanks

There's a plug quite visible on top just a little behind and left of the digital display module on the TS830, that works loose with vibration (like, oh, when you're moving the rig around to work on it). You'll see the wires running into the display module. Give it a gentle push and see if your display comes on.

I dont know what KW had in mind with routing RLR to the PLL board. I have never seen any TS830 with RLR at the PLL board. All including original 10 million series units there is no RLR line to Conn 8. There is however a solder trace and empty solder pad on all the boards I have seen. I dont know if the documentation is simply wrong or if there was some original design thought that was never carried out. Kind of unusual for the schematic and the abbreviation chart to both be wrong.

That being said RLR has nothing to do with having no Marker signal so not sure why concerned about the empty Molex Conn 8 position unless just curiosity?

RLR is 9vdc line that is keyed by the Aux relay on the Audio board. It feeds several circuits including the variable bias voltage for the VBT Osc vari-cap diode, the Mode switch to provide bias for IF filter switching diodes, and to the RF board to bias on transistor switch Q5 in RX mode to provide a ground path for the mosfet source resistors of the receiver RF amp, the Buffer amp, and the RIF Mixer.

Pretty easy to troubleshoot loss of Marker signal if you have an O-scope
1. Wiggle and/or clean three Molex connectors (2 on PLL board and 1 on RF board)
2. Measure Marker output with O-scope at Conn 4 on PLL board
3. If no signal apply temporary ground to MS terminal at PLL board. MS supplies ground for the 25khz multivibrator transistors and buffer amp. No ground and no Marker output.
4. If good Marker signal on O-scope at PLL board then move scope to RF board Conn 4. If good Marker signal here then possible bad solder at Molex conn pin 2 or bad diode D1 (not a common failure).

Does the digital display work and approx agree with the VFO? If so it tells you the 10mhz clock is working. I have seen cases where the 10mhz crystal pins were not soldered properly.

You can follow the 10 mhz clock at TP-2 on PLL board where should see 1mhz and at Pin 11 of Q25 where should see 100Khz.

Common failures are the associated molex connectors (either dirty or bad solder connections at the pins) and bad solder connections at the 10 mhz crystal pins. I assume the receiver is working and you are just missing the Marker signal.

Giving this some more thought.

If you look at the PLL schematic it is possible that KW originally planned to key the Marker on and off by applying 9vdc from RLR line thru resistor R152 and then decided to key it by grounding the Emitters rather than switching the Collector supply voltage. Also, series resistor R152 is mounted on the foil side of the board which usually means a after thought or change.

I am not sure what difference turning on the multivibrator transistors and buffer amp transistor by grounding emitter vs switching the collector supply voltage would make other than it is common to leave the collector or drain voltages of active devices on all the time and key the emitters or source leads. I cant think of any operational differences in the oscillator performance.

I suspect this is done as it is easier to power a bus that feeds multiple active devices on a board and to switch the individual devices in the emitter or source leads.

I dont know if the documentation is simply wrong or if there was some original design thought that was never carried out. Kind of unusual for the schematic and the abbreviation chart to both be wrong.

That being said RLR has nothing to do with having no Marker signal so not sure why concerned about the empty Molex Conn 8 position unless just curiosity?

RLR is 9vdc line that is keyed by the Aux relay on the Audio board. It feeds several circuits including the variable bias voltage for the VBT Osc vari-cap diode, the Mode switch to provide bias for IF filter switching diodes, and to the RF board to bias on transistor switch Q5 in RX mode to provide a ground path for the mosfet source resistors of the receiver RF amp, the Buffer amp, and the RIF Mixer.

Pretty easy to troubleshoot loss of Marker signal if you have an O-scope
1. Wiggle and/or clean three Molex connectors (2 on PLL board and 1 on RF board)
2. Measure Marker output with O-scope at Conn 4 on PLL board
3. If no signal apply temporary ground to MS terminal at PLL board. MS supplies ground for the 25khz multivibrator transistors and buffer amp. No ground and no Marker output.
4. If good Marker signal on O-scope at PLL board then move scope to RF board Conn 4. If good Marker signal here then possible bad solder at Molex conn pin 2 or bad diode D1 (not a common failure).

Does the digital display work and approx agree with the VFO? If so it tells you the 10mhz clock is working. I have seen cases where the 10mhz crystal pins were not soldered properly.

You can follow the 10 mhz clock at TP-2 on PLL board where should see 1mhz and at Pin 11 of Q25 where should see 100Khz.

Common failures are the associated molex connectors (either dirty or bad solder connections at the pins) and bad solder connections at the 10 mhz crystal pins. I assume the receiver is working and you are just missing the Marker signal.

Bob,

My "service manual" is 1981-3. The "PLL" schematic on Pg 17, shows NO CONNECTION on Connector 8, pin 2. However, the "whole rig" schematic on Pg 63, does show a connection. As noted by other group members...the schematics are NOT always 100% accurate.

I asked a couple of others to check their 830S's and their connector # 8 going to the PLL board is the same as what I posted.

Hi Joe - Thanks for the quick reply and clarification. The service manual I have shows the below. Must be more versions:

45692. A simple exercise to calculate the approximate final amplifier metering circuit voltage and current

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-04 15:30:19 UTC
From: Mike
Topic: 45692 Message: 45692

The following exercise is for the newbies so please, all you experienced members let the newbies and people who are learning answer the questions.

Exercise data:
The exercise is based solely on the TS-520 and/or the TS-820 final amplifier and meter circuit.

The transceiver's meter internal resistance is 600 ohms.

The IP meter multiplier resistor is 3.3K.

The final amplifier cathode resistors are 10 ohms each (2 x 10).

The meter switch is set to IP position.

The final amplifier cathode current is .225 amps.

Based on the above values:

1. What is the current that's flowing in the IP meter circuit?

2. What is the voltage drop across the 3.3K meter multiplier resistor?

3. What is the DC voltage that is applied to the meter?

I am fully aware that resistor values are not always what the schematic values indicate. However, for the purpose of this simple exercise, the resistor values are as stated.

Topic: 45693 Message: 45693

The TS-520 voltage chart, page 45, states the cathode voltage, pin 1 of V1 and V2 (S2001) final tubes is 1.3VDC. Based on that, what is the cathode current in the final amplifier?

Subject: [TS-520_820_530_830] Whackamole & Pin2 on PLL connector 8

As I try to resurrect this TS830S that someone butchered, I find it is like playing whackamole. I finally got the receiver to work quite well & the S meter now responds with appropriate readings (all bad connections of some sort). But then I find the CAL won't produce a signal. I trace that down to a bad ground, probably caused by me when I had the front panel off. But as I trace the orange CAL switch wire back to pin 3 on connector 8 on the bottom side of the PLL board, I notice that #2 wire is completely missing in that connector. The pin hole inside the connector is empty & there is no loose wire anywhere nearby. The pin is named RLR on the schematic. Any comments? Late engineering change? This radio is wearing me out. Thanx - Bob

Hi Terry,
I am concerned, because of the other butchered areas of my radio. I keep finding stuff. I have yet to try the transmitter. This is my first Hybrid; first tube transmitter.

I was given this TS830 & out of respect for it and the jerk (said playfully), I am trying my limited best to get it going again.

I already figured out the cal problem by simply just grounding the orange wire & the cal fired right up. Then I checked the cal switch itself & it is good. So the ground coming off the switch is bad. Very ez to fix.

The display still needs work as it still dims on occasion. I hope to try the transmitter soon. - 73 - Bob

Looks like I am ready to transmit, 'cept for a mic. I'll have to look around. I might have a 4 pin connector around somewhere. Anyone have a decent MC50 for sale? Just missed one for $50 on QTH.

I dipped my first PLATE!! Now I am a super Dip! I have read about the term for ever, but I have never seen it done. I ran it into a dummy load I built. Seemed to tune up fine. RF meter was way out of adjustment, so that was a scare. Almost bent the needle. I put it at the 2/3 position as suggested. Now I should check to see if the finals were ever neutralized. Another new experience about to unfold.

I am still shakey on the tune thing. Scary hitting send the first time. Actually, when I hit SEND, Ip went NEGATIVE, not 60mA. Turns out it was a dirty meter switch!! Definitely naming this 830: Whackamole.

OK Bob if rig has been butchered then I understand then why you might be concerned about no RLR wire at the PLL board.

You would think that you could depend on the schematic being correct but unfortunately not always the case with any of the hybrids.

Anytime you have a question about the as-built vs the schematic it is good not to make any assumptions and to come here and ask.

There are some really hammer fisted people doing some hack jobs on these rigs. Ill conceived mods and poor implementation. I just had a TS520 here that I bet I got about 10 or more solder blobs/balls fall off the circuit boards or lodged in the wiring harness and wire insulation within the harnesses melted by the iron tip.. Sad.

Have fun
Terry K9TW.

Topic: 45692 Message: 45700

Ok Mike heres what I came up with,

After getting my cathode voltage of 1.125v for number 1) I used I = 1.125/3900 = .000288. 3900 being the total resistance of the IP meter circuit. Number 2)The voltage drop across the 3.3k meter multiplier resistor is E = .000288(3300) = .9504. For number 3) I subtracted 1.125 from .950 (I dropped the 4) and got .175

Thanks for another great exercise.

Daniel

Approx values (out of circuit) are:

Primary
Resistance = 0.25 ohms
Inductance = 0.85uhy

Secondary
Resistance = 1.00 ohms
Inductance = 15.5uhy

You can also perform a excitation test out of circuit:
1. Inject 5mv @ 10.00mhz into the Primary winding. That is 10 mhz and not 1 mhz.
2. Connect RF millivolt meter or O-scope across the Secondary.
3. Adjust the slug tuned core for maximum RF output voltage. Should see approx 40mv with the core approx 1 turn outside the top of the shield can.

I would never remove L41 without testing in circuit to confirm it is bad. The above is suggested post rewind testing prior to re-installing in the rig.

Daniel,

Here's one for you.

If the meter's internal resistance is 600 ohms and the cathode voltage
is 1.75VDC, what is the meter's FSD voltage rating?

You can keep your answer to 3 decimal places and round off if you like.

45705. TS830S Plate control adjustment

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-04 21:40:15 UTC
From: <dlacroix@...>
Topic: 45705 Message: 45705

On 15 meters when adjusting the Plate control, the position where I get the best plate current dip is outside the '21' marking and almost in the '28' marking on the dial. On 20 meters it is within the '14' marked section as expected. Could this be an indication of a problem or just an oddity? I haven't received any reports of problems with my signal on 15 meters..

Thanks,
Dave - WB0SD

Hi Terry,
I have a IC-751A and the very first step in the SM alignment process is incorrect! So I know what you are talking about. For Engineering company's, Ham radio documentation to often sucks. Look at the schematic on a new MC-60A mic & you will find an error that has been there forever. Kenwood still sends out the bad schematic. Where I worked, we made certain that every engineer read the support material before being published. This did not prevent all mistakes, but the peer pressure was very high along with the bad publicity. Done with rant.

But it does bring me to another question & that is the alignment of the Ant/Mix/RF on the 830. If I follow the instructions, the CAL tone is nulled at the prescribed frequencies, is it not?

Bob,

Sorry to jump in, but...the answer is... no.

  Look on upper left corner of Pg 28 in the 830S "instruction manual." You adjust for "max S meter reading"(ant & mix coils), or take a look at Pg 36, step 16 in the "service manual".
The "transmit drive coils" are adjusted per instructions on Pg 28 of the "instruction manual" or Pg 37, Step 18 in the "service manual" Make sure you have the proper "termination" at the SO-239 connector at the back....ie 50 ohm dummy load works great.

My experience has been that you may NOT get a good "cal signal" directly at the indicated frequency at first(depending on who has messed with it prior...which we know someone other than you has)...you may have to go off frequency a bit...adjust associated coils...then try and dial back to the indicated frequency and re-tune them. If you have a signal generator...so much the better.

Mike I think I'm stumped. I'm not sure what an FSD rating is. I believe FSD stands for full scale deflection, and with a cathode voltage of 1.75 and a meter resistance of 600 ohms the voltage applied to the meter be .270 volts which would give you and meter current of 350ma and that's as high as the meter goes but I'm not sure I'm answering your question.

Daniel

Daniel,

Here's one for you.

If the meter's internal resistance is 600 ohms and the cathode voltage is 1.75VDC, what is the meter's FSD voltage rating?

You can keep your answer to 3 decimal places and round off if you like.

The following exercise is for the newbies so please, all you experienced members let the newbies and people who are learning answer the questions.

Exercise data:
The exercise is based solely on the TS-520 and/or the TS-820 final amplifier and meter circuit.

The transceiver's meter internal resistance is 600 ohms.

The IP meter multiplier resistor is 3.3K.

The final amplifier cathode resistors are 10 ohms each (2 x 10).

The meter switch is set to IP position.

The final amplifier cathode current is .225 amps.

Based on the above values:

1. What is the current that's flowing in the IP meter circuit?

2. What is the voltage drop across the 3.3K meter multiplier resistor?

3. What is the DC voltage that is applied to the meter?

I am fully aware that resistor values are not always what the schematic values indicate. However, for the purpose of this simple exercise, the resistor values are as stated.

No... you will adjust for maximum S-meter indication. The Marker or Xtal Calibrator is your signal generator. You can find the procedure in the Maintenance Section of your TS830 operating manual.

Should be able to get approx S9 indication assuming the S meter span trimmer is reasonable well set.

Daniel, your answer is correct. "FSD" means "Full Scale Deflection", the "S" meaning "Scale" which is the maximum "scale" indicator on the meter.

I should have not used the word "rating", only FSD, my fault but you still answered the question correctly. It's obvious you have been studying as you seem to be answering the questions "correctly" without any problem.

I can speak for myself in that I went through the same basic learning process you are going through. Keep going, study, and experiment with simple circuits. That's how you learn. You will make mistakes and there will be times when you ask yourself, "what the hell was I thinking??" I know, been there done that, many times!!! You will have "brain farts" where you just can't seem to get it. That's when you stop, do something else, then come back later and you will "get it".

I'm very impressed Daniel, you're doing very well!! Keep it up, study, read, and don't be afraid to make a mistake.

Thanks Joe & Terry. I took the settings as literal, when in actuality you have to off tune to get the maximum S meter reading. An indeed, the S meter is right around S9. Thanks for helping an 830 newbie. I just ordered a mic for it, so I should be able to check out SSB next week. - 73 Bob

PLEASE CORRECT THIS IF IT IS WRONG. RON: DO NOT TAKE MY SOLE WORD AS GOSPEL FOR THIS. I'm doing my best reading some pretty crappy PDF file text from a scanned parts list, but I am NOT one of the gurus on this topic by ANY means. "I am only an egg. Grokking will come." I'm just another user, in other words, and I don't think you could go too far wrong with these specifications (below) if nobody else chimes in with better information. If I were going to get a replacement for the cap on MY 520SE X43-1110-00 HV board, it is what I would look for and use without any real qualms. I'm almost positive that there would be no ill effects, positive enough to, as I said, use one myself if it ever went out on me.

From the bad scan of the Service Manual, in the parts list, there is a part identification header, which is about as cryptic and poor a piece of documentation as I have seen since I got my USAF discharge.

From that, and with my best guess from the circuit parameters on that board, it looks as if that was spec'ed at Kenwood as a 0.01 microFarad ceramic disk capacitor with a 1.8 kilovolt working voltage, and a Type II temperature coefficient. I think (from some textbook pages I've dived into to double-check) that the type you should use for this application would be a "Z5E" which changes less than five percent over the range of temperatures from 10 to 85 degrees Centigrade. (Cool to really hot but not quite boiling.) This ought to be slightly better than the original one, as a matter of fact.

In any case I think K4EAA has some replacement 0.01 microFarad 2 kV Z5E capacitors for sale on his web site. Also some of the other repair people here ought to be able to source them for you.

You should be able to get this part from about any decent supplier,

http://ca.mouser.com/ProductDetail/Xicon/140-202P9-103K-RC/?qs=sGAEpiMZZMt1mVBmZSXTPCB4s6x5SlOXz7Jdi%252biSDKM%3d

I think this one from Mouser ought to do the trick.

PLEASE CORRECT ME IF THIS IS IN ANY WAY MISLEADING OR JUST PLAIN WRONG.

But that's what I would be ordering if it was mine to repair. Best I can do for you, let's just hope one of the high-forehead types (or

somebody with a full Kenwood parts list!) pops in with a better answer.

Peter,

You can contact Gordon, directly. I'm unsure of the price, but you will have to send him your old L41 as well, this way he can then re-wind another and have it waiting for another user.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Approx values (out of circuit) are:

Primary
Resistance = 0.25 ohms
Inductance = 0.85uhy

Secondary
Resistance = 1.00 ohms
Inductance = 15.5uhy

You can also perform a excitation test out of circuit:
1. Inject 5mv @ 10.00mhz into the Primary winding. That is 10 mhz and not 1 mhz.
2. Connect RF millivolt meter or O-scope across the Secondary.
3. Adjust the slug tuned core for maximum RF output voltage. Should see approx 40mv with the core approx 1 turn outside the top of the shield can.

I would never remove L41 without testing in circuit to confirm it is bad. The above is suggested post rewind testing prior to re-installing in the rig.

Dave,

A number of factors can come into play, it can be subject to actual frequency being tuned, the screws on the shaft may have come loose at some stage and wasn't re-aligned properly, list can go on and on.

Try and tune in the centre of the band into a dummy load. Do this for each band and record your results. From there you can then tune on air on the same freq for each of the bands and compare against your dummy load, report back and we can re-assess. The tuning for most parts will be within the raised white marks on the face plate.

EG: The other day I tempted "Murphy" to pay me a visit by saying to a good friend on the forum my beam has been perfect for the last 19 years, especially with all the high winds recently going through the area. I was listening for K9W, (Wake Island Dxpedition) and tried to tune my radio for 15m, with a slight breeze the SWR and power went all over the place, the load positions were so far out of normal range. I now have to get a cherry picker in and work out where the problem is (most prob trap on driven element) other two bands were perfect. Radio tuned up perfect into dummy load, normal tuning marks on dial.

Just set the Drive control to 1200 and set the VFO to the listed frequency and follow the band sequence in Table 6-1 as there is some interaction.

Your objective is to have the ALC peak in Tune mode and the Receiver back ground noise to peak at the same position of the Drive Control as you move from one end of the VFO tuning range to the other.

There is no reason to hunt for the current max settings.

Just follow the procedure as written in the Sect 6 Maintenance of the operating manual and remember need the Heaters on to do the Drive coils. I dont think the manual states this and may not be intuitive.

Using Table 6-1 sequence make one pass and then repeat. After doing the Coil Pack suggest you do the IF transformers and recognize some may have little effect.
Better to do complete using the Service Manual but need good RF sig gen for this so just do the short version.

You wont be able to accurately do the S-meter cal without a RF sig gen with calibrated -73dBm (50uv) output, but you can just adjust the span pot for an S9 indication with the Marker signal and Drive Control peaked at 1200. Do that at 14.2mhz and you will be close enough to give on air antenna and amplifier comparisons etc.

Not quite correct. The disc ceramic cap is a "2H" which is a 500 wvdc cap.

You generally have two ways to determine capacitor ratings. 1. Look at parts list and take the part number to a mfg capacitor data sheet to decode it OR 2. Analyze the circuit and determine the component function and operating parameters.

The cap is a rf bypass cap so you dont have any rf ripple applied to your panel meter when reading the anode voltage in the HV position of the meter.

This circuit is a simple 20/1 voltage divider that Mike has been discussing. 900 vdc is applied to the top end of the divider and at the junction of the 2 meg and 100k resistors you will measure approx 44vdc when meter is not in the HV position. So no reason to use a 1.8kv wvdc cap for this application.

When the meter switch is placed to HV position the internal R of the meter is placed in shunt across the 100k resistor and now the divider becomes approx 3400/1 (2meg/600) so the voltage at the junction is now 44/3400 or 0.13vdc. Remember Dan just told us the meter requires 0.27vdc for FSD. 0.13vdc will cause meter to deflect to approx 900vdc.

So the voltage that the meter movement and the disc ceramic by-pass cap sees in service ranges from a high of approx 44vdc to low of 0.13vdc. Using a 1.8kv cap for this application would be overkill but if in your junk box go for it.

My real question is ...Why do you think this cap needs replacement? How did you troubleshoot to determine it was bad? If it is burned up I would take close look at the three 680k resistors and/or make sure no carbon path across them.

OK still not quite correct! Math error! I told you the "Calculus" got the best of me!

Voltage at mid point of divider will be 3400/1 ratio when meter is placed in HV position so 900/3400 = 0.265vdc and NOT 0.13vdc. 0.13vdc would give you approx mid-scale deflection or 500vdc indication.

In practice if you measure the voltage you will find it may be as low as approx 0.23vdc. This is because the meter string divider resistors are not precision resistors and the actual divider ratio will vary. Meter is not intended as a precision HV voltmeter. It is there for approx calcs of dc input power and to see if you have 450vdc vs 900vdc.

Sorry about that.

Terry

Ron:

Nothing to be sorry about. I am trying to understand your thought process.

You can throw that disc cap over your shoulder and radio will work fine. How did you determine it was open? This low a value cap you will need a VOM or VTVM and if you blink you can miss the very brief meter flick on the resistance range.

Other way to check it is lift the ground end and connect your VTVM to the free end and set VTVM on lowest DC voltage scale and power on rig and watch for the very brief dc voltage kick. If you get no kick then cap is open and if constant low value of dc then cap is leaky.

If the 680k string was shorted or carbon track to mid point of the divider then you could have applied 900vdc to this cap and to your panel meter. This is why anytime you use this method of measuring HV you use a string of series resistors instead of just one resistor. Not likely for the entire string to short or track across.

Does your panel meter work in RX mode for S-meter indication? If not report back and can tell you how to test your meter.

As to no cathode voltage on the 6146 Finals you must have the rig keyed and dc current flowing to have any voltage on the 6146 cathodes. Need good cathode meter shunt resistors to complete the path and proper operating bias on the control grids and proper screen grid voltage and heaters on.

Can you set the resting or zero signal plate current to 60ma? If so, then you will have cathode voltage.

Terry ,,, I have resting bias , maybe I used the wrong terminology what I don't have is any voltage in the hv cage (out the top of the 6146's) I've changed the 6146's but still dead and also I haven't had it hooked up to an antenna so I don't know if I have any voltage to meter in rf mode I checked the cap with a vtvm, and no kick at all
Also I am waiting on an order of resistors to continue the repair of this mess of a radio but getting great practice getting it going and having fun doing it !!!

Yes, that's part of learning standard safety precautions which every ham should study/learn and adhere to at all times when working around voltages, regardless of the voltage level, AC or DC.

The link below discusses the effects electricity, both AC and DC, has on the human body. A good read for all hams.

Ron

One more thing. I know you replaced the 56k divider resistors. They only effect screen grid voltage in Tune mode. Will still have output in CW mode when they are open as will have full screen grid voltage applied.

I think you may be confused on how the 6146 anode voltage is supplied. The HV meter board that you some how gravitated to has nothing to do with that. I know you see 800 and HV terminals at that board so that may have confused you into thinking this is the supply path for the 6146 anodes?

It is just a board where you divide the screen voltage in half and a board where you sample the 900vdc (800) and supply a very low dc voltage (HV) to your panel meter. Board should have nothing to do with no anode voltage unless it would short out and develop a bolted fault to ground and then would blow the rigs power transformer primary fuse.

The 900vdc anode voltage leaves the HV rect board and is applied directly to the tube anodes thru the small VHF choke and large RF choke in the PA Cage and thru the parasitic suppressors to the anode caps.

OK the 900vdc does not come out the top of the 6146 finals. The 900vdc is applied there.

You can start measuring in the PA cage and work back to the HV rect board or work the other way. In either case you must observe good safe work practice measuring this 900vdc.

If you have little experience or rusty I suggest you connect the DMM or VTVM first and then power on the rig to take the measurements.

You can also do a good visual inspection with rig unplugged and HV caps discharged.

Visual includes:
1. Is large RF choke in PA cage burned black or any signs of over heating?
2. Is the small VHF choke at base of large choke burned?
3. Is the RF bypass cap at base of large choke burned or blown open
4. Are the rupture vents on the two HV filter caps blown or leaking tar like or dry white powdery deposits. Vents can also be bulged out.

Voltage measurement:
1. Connect the ground lead of your volt meter to the chassis ground post
2. Connect the plus meter lead probe thru a good jumper test lead to the end of parasitic chokes that feed the anode caps.
3. Make sure the end of the jumper lead to your meters plus probe is covered so you cannot make accidental contact.
4. Power on the rig and record the voltage
5. Down power the rig and make sure voltmeter reads zero and then remove the test jumper.
6. Move to the bottom of the large plate choke and connect the test jumper
7. Place self in clear and re-power the rig.
8. Repeat this process all the way back to the HV rectifier board.

Very easy but must be aware of hazards and control your test leads.

Some say put one hand in pocket and that sounds good but not a real practical approach as need free hand to hold flashlite, change meter range etc.

Safest it to connect meter and then put self completely in clear and power on rig and record the voltage and then down power. Must make sure have good positive mechanical connection that wont pop off and must have the probe and test lead interface covered so you dont forget and accidently contact it.

Not trying to insult you. You can move probe from point to point using the meter test prod with rig powered if you are experienced, but still must be constantly aware of what you are doing so you dont slip off or bridge things.

Even today after all these years when I am dealing with anode voltage in an RF amp PA or HV power supply I connect the voltmeter with unit down powered and put myself in safe position and then power on to get the reading. Want to live another day to play!

Ron:

I may be a little hard on you.

The actual as built is the 900vdc leaves the HV Rect board on a short red jumper to the HV metering board. From there it leaves on a HV cable that looks like the center of piece of coax and runs to the black terminal strip in the PA cage and on to the small VHF choke and main RF choke.

So I guess it is possible that you might think that if you had no 900vdc anode voltage that the problem could be on that HV metering and SG divider board.

I would not reach for that as I know the voltage is derived from the voltage doubler rectifiers that are on the HV Rect board.

So when I said the 900vdc directly goes from HV Rect board 800 terminal post to the Plate choke that is not technically correct. It goes to the HV metering board and from there on to the PA cage.

As long as you are not blowing the primary fuse focus your efforts on the Anode supply path and not the HV metering board. You of course will need to replace the bad 680k resistors and the bypass cap and do a very good visual to ensure no carbon tracks on this board.

I sure hope you have not applied 900vdc to your panel meter. Will cross that bridge when you find why you have no 6146 anode voltage.

A damaged L1 of the BCB filter on the RF board make sense, but accidental Transmit should never have got to L1 at RIF input to common gate RF amp on the IF board. If it did the RIF Mixer on RF board would have been damaged.

I would never remove L1 or any other component on IF board until replacing L41 and doing good Coil Pack alignment and RF and IF alignment.

DId you replace L1 on IF board? It is there for a reason.

You can start measuring in the PA cage and work back to the HV rect board or work the other way. In either case you must observe good safe work practice measuring this 900vdc.

If you have little experience or rusty I suggest you connect the DMM or VTVM first and then power on the rig to take the measurements.

You can also do a good visual inspection with rig unplugged and HV caps discharged.

Visual includes:
1. Is large RF choke in PA cage burned black or any signs of over heating?
2. Is the small VHF choke at base of large choke burned?
3. Is the RF bypass cap at base of large choke burned or blown open
4. Are the rupture vents on the two HV filter caps blown or leaking tar like or dry white powdery deposits. Vents can also be bulged out.

Voltage measurement:
1. Connect the ground lead of your volt meter to the chassis ground post
2. Connect the plus meter lead probe thru a good jumper test lead to the end of parasitic chokes that feed the anode caps.
3. Make sure the end of the jumper lead to your meters plus probe is covered so you cannot make accidental contact.
4. Power on the rig and record the voltage
5. Down power the rig and make sure voltmeter reads zero and then remove the test jumper.
6. Move to the bottom of the large plate choke and connect the test jumper
7. Place self in clear and re-power the rig.
8. Repeat this process all the way back to the HV rectifier board.

Very easy but must be aware of hazards and control your test leads.

Some say put one hand in pocket and that sounds good but not a real practical approach as need free hand to hold flashlite, change meter range etc.

Safest it to connect meter and then put self completely in clear and power on rig and record the voltage and then down power. Must make sure have good positive mechanical connection that wont pop off and must have the probe and test lead interface covered so you dont forget and accidently contact it.

Not trying to insult you. You can move probe from point to point using the meter test prod with rig powered if you are experienced, but still must be constantly aware of what you are doing so you dont slip off or bridge things.

Even today after all these years when I am dealing with anode voltage in an RF amp PA or HV power supply I connect the voltmeter with unit down powered and put myself in safe position and then power on to get the reading. Want to live another day to play!

OK Ron....If you have replaced the small choke, bypass cap, and coupling/blocking cap in the PA cage and the big choke is not hurt and the parasitic suppressors have good soldering then you should have good anode voltage at the plate caps.

If you are certain that you had resting plate current with no 6146 Anode voltage you had to have Screen Grid voltage. Never good to run screen grids without the anode energized as resulting screen grid current can exceed the screen grid dissipation of the tube. None of this aligns with your report that you had no cathode voltage. Have to have cathode voltage if you had resting plate current. For meter to indicate in IP position have to have IR drop across the cathode meter shunt resistors.

You may have damaged 6146 finals if you truly had no Anode voltage which would be the case with no small vhf choke at base of big choke.

Before installing another set of finals you may want to pull these and leave out and measure the operating bias and screen grid voltage at the tube socket pins. If good then make sure have anode voltage at top of the plate choke. Have to be very careful with the anode caps dangling in the air. If all voltages available then can install new tubes or try the ones you pulled.

Ron:

I may be a little hard on you.

The actual as built is the 900vdc leaves the HV Rect board on a short red jumper to the HV metering board. From there it leaves on a HV cable that looks like the center of piece of coax and runs to the black terminal strip in the PA cage and on to the small VHF choke and main RF choke.

So I guess it is possible that you might think that if you had no 900vdc anode voltage that the problem could be on that HV metering and SG divider board.

I would not reach for that as I know the voltage is derived from the voltage doubler rectifiers that are on the HV Rect board.

So when I said the 900vdc directly goes from HV Rect board 800 terminal post to the Plate choke that is not technically correct. It goes to the HV metering board and from there on to the PA cage.

As long as you are not blowing the primary fuse focus your efforts on the Anode supply path and not the HV metering board. You of course will need to replace the bad 680k resistors and the bypass cap and do a very good visual to ensure no carbon tracks on this board.

I sure hope you have not applied 900vdc to your panel meter. Will cross that bridge when you find why you have no 6146 anode voltage.

Topic: 45740 Message: 45740

As I'm reading up transistors as switches and snap acting relay circuits, and biasing, I'm also looking at the schematic and I noticed the transistors Q7, Q8, Q9 that are labeled off to the side that labels the pins doesn't have the Base as the center pin. My question is on the schematic itself is the Base the center input? Im asking because the transistor symbols ive seen when reading about them has always had the base in the center with the collector and the emitter perpendicular to the base. I wasn't sure which labeled voltages on the schematic symbols go to which pins on the actual transistors.

Daniel

45741. RE: Relay transistor question

Topic: 45740 Message: 45741

Yes on the schematic the base is the center lead and the bar on the transistor symbol. The emitter is the arrow symbol and arrow direction tells you if the device is a PNP or NPN transistor. Collector is the other lead.

You always need to look at the X-ray views of the boards to see the device physical lead or pin out configuration. Have to be careful when using a sub device as often Collector will be the center lead and not the Base lead. Often have to cross leads over with caution so you dont short them together.

Have to remember that the schematic tells you nothing about the physical construction. The schematic and symbols used show you how it works electrically.

If you do not have the Service Manual you need to download one so you have the Xray views. The Xray views also have all the devices at the bottom of the drawing showing you the CBE and DSG lead configs.

In the electrical world they use schematic equivalent called Elementary diagram and to see the actual routing of the wires to the devices like breakers, contactors, and relays, timers, pressure switches etc you use a corresponding Wiring Diagram.

KW does not provide wiring diagrams and wire color coding. KW also did not do us a favor by leaving active devices mounted a little above the PC board to allow test meter connection to CBE or DSG. Sure would have made life easier.

Terry , the meter indicated a resting bias and I adjusted it to 60ma after doing the repairs to pa cage the meter is resting at 230 ma I removed the finals then measured the pin voltage 15 vdc falling to 3vdc on pin 1 of final. V1 also before repairing the pa cage there was speaker noise now there is none I don't know if this is relevant or not . I can adjust bias up but not down now thanks

Terry,

Ok thanks that's what I thought but I wanted to double check. a couple more questions while Im looking at the schematic, The pins on the FIX VOX board are labeled but some Im not sure of their meanings, Ill stick to the ones we've discussed and the few others attached to the relay circuit. The 14A, not sure about the A, SS, VS, and TO. Also the block diagram has a line drawn from Q5 to Q7 but I don't see any connection on the schematic. and Q7, Q8 are labeled what looks like the word SHUMIT on the block diagram, some letters are hard to read, and Q9 is labeled RL CONT. I think RL stands for Relay but im not sure about the cont.

Thanks again,
Daniel

Ron:

Your note is a bit cryptic.

I thought you had bad meter string resistors or possible carbon path. Did you repair meter board before energizing the rig? If not sure would not put meter in HV position.

Are you saying that when you key the rig in SSB mode with mic gain turned down and the meter in Ip position that you cannot adjust the resting plate current below 230ma with the bias voltage adjust pot run thru its range?

Did you measure the operating bias voltage on the Pin 5 control grids? If operating bias voltage is not correct can cause high resting plate current. Should be approx -55vdc with rig keyed. You should be able to set the bias voltage to -55vdc with the bias voltage adjust pot on side of rig. If you cannot you need to check -C.

Give me more detail on when you are seeing this 230ma IP. You do not want to leave standing 230ma on the finals for more than a few seconds.

If you removed the two 6146 final tubes there would be no reason to measure the cathode voltage at Pin 1. You should not expect any cathode voltage with no tube in the socket?

If you measured the Cathode voltage at Pin 1 with finals in the socket and rig keyed you would have to have open cathode resistors or bad ground to see cathode voltage of 15vdc or more. Any time the cathode is lifted from ground it will try to rise toward screen grid voltage (typically over 100 vdc). If you are using a DMM you are completing the path from cathode to ground with the meter so the voltage will drop down once you connect the meter. With rig down powered and unplugged measure the resistance from Pin 1 to ground and should see approx 5 ohms.

I told you to measure the screen grid voltage and operating bias voltage with tubes removed. You do that with rig keyed in CW mode and SG switch on. I did this so you would not damage tubes again if you had no operating bias. If you dont have bias the tubes will go into thermal runaway.

Terry K9TW

On Tuesday, November 5, 2013 10:30 AM, "wagstw46@..." <wagstw46@...> wrote:

Ron:

I may be a little hard on you.

The actual as built is the 900vdc leaves the HV Rect board on a short red jumper to the HV metering board. From there it leaves on a HV cable that looks like the center of piece of coax and runs to the black terminal strip in the PA cage and on to the small VHF choke and main RF choke.

So I guess it is possible that you might think that if you had no 900vdc anode voltage that the problem could be on that HV metering and SG divider board.

I would not reach for that as I know the voltage is derived from the voltage doubler rectifiers that are on the HV Rect board.

So when I said the 900vdc directly goes from HV Rect board 800 terminal post to the Plate choke that is not technically correct. It goes to the HV metering board and from there on to the PA cage.

As long as you are not blowing the primary fuse focus your efforts on the Anode supply path and not the HV metering board. You of course will need to replace the bad 680k resistors and the bypass cap and do a very good visual to ensure no carbon tracks on this board.

I sure hope you have not applied 900vdc to your panel meter. Will cross that bridge when you find why you have no 6146 anode voltage.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com mailto:TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK the 900vdc does not come out the top of the 6146 finals. The 900vdc is applied there.

You can start measuring in the PA cage and work back to the HV rect board or work the other way. In either case you must observe good safe work practice measuring this 900vdc.

If you have little experience or rusty I suggest you connect the DMM or VTVM first and then power on the rig to take the measurements.

You can also do a good visual inspection with rig unplugged and HV caps discharged.

Visual includes:
1. Is large RF choke in PA cage burned black or any signs of over heating?
2. Is the small VHF choke at base of large choke burned?
3. Is the RF bypass cap at base of large choke burned or blown open
4. Are the rupture vents on the two HV filter caps blown or leaking tar like or dry white powdery deposits. Vents can also be bulged out.

Voltage measurement:
1. Connect the ground lead of your volt meter to the chassis ground post
2. Connect the plus meter lead probe thru a good jumper test lead to the end of parasitic chokes that feed the anode caps.
3. Make sure the end of the jumper lead to your meters plus probe is covered so you cannot make accidental contact.
4. Power on the rig and record the voltage
5. Down power the rig and make sure voltmeter reads zero and then remove the test jumper.
6. Move to the bottom of the large plate choke and connect the test jumper
7. Place self in clear and re-power the rig.
8. Repeat this process all the way back to the HV rectifier board.

Very easy but must be aware of hazards and control your test leads.

Some say put one hand in pocket and that sounds good but not a real practical approach as need free hand to hold flashlite, change meter range etc.

Safest it to connect meter and then put self completely in clear and power on rig and record the voltage and then down power. Must make sure have good positive mechanical connection that wont pop off and must have the probe and test lead interface covered so you dont forget and accidently contact it.

Not trying to insult you. You can move probe from point to point using the meter test prod with rig powered if you are experienced, but still must be constantly aware of what you are doing so you dont slip off or bridge things.

Even today after all these years when I am dealing with anode voltage in an RF amp PA or HV power supply I connect the voltmeter with unit down powered and put myself in safe position and then power on to get the reading. Want to live another day to play!

On Nov 5, 2013, at 8:52 AM, <wagstw46@... mailto:wagstw46@...> wrote:

Ron:

Nothing to be sorry about. I am trying to understand your thought process.

You can throw that disc cap over your shoulder and radio will work fine. How did you determine it was open? This low a value cap you will need a VOM or VTVM and if you blink you can miss the very brief meter flick on the resistance range.

Other way to check it is lift the ground end and connect your VTVM to the free end and set VTVM on lowest DC voltage scale and power on rig and watch for the very brief dc voltage kick. If you get no kick then cap is open and if constant low value of dc then cap is leaky.

If the 680k string was shorted or carbon track to mid point of the divider then you could have applied 900vdc to this cap and to your panel meter. This is why anytime you use this method of measuring HV you use a string of series resistors instead of just one resistor. Not likely for the entire string to short or track across.

Does your panel meter work in RX mode for S-meter indication? If not report back and can tell you how to test your meter.

As to no cathode voltage on the 6146 Finals you must have the rig keyed and dc current flowing to have any voltage on the 6146 cathodes. Need good cathode meter shunt resistors to complete the path and proper operating bias on the control grids and proper screen grid voltage and heaters on.

Can you set the resting or zero signal plate current to 60ma? If so, then you will have cathode voltage.

OK what does that tell you? - 1.5vdc when? In RX or in TX?

It appears you have lost -C or you have a bad bias voltage adjust pot. Two most common failures.

Can work way back from Pin 5 or go to HV Rect board and work toward the tubes.

At tubes you have a series resistor and choke that could be bad but with -1.5vdc would not be open but could be high resistance. . From there you go to the FG terminal post on the RF board. Some series resistors in ALC base bias network but seldom go bad. From there you have VR1, VR2 and VR3 and the bias adjust pot and the -C terminal post. From there - C lead routes back to Rect Board.

On Nov 5, 2013, at 3:59 PM, <wagstw46@... mailto:wagstw46@...> wrote:

OK Ron....If you have replaced the small choke, bypass cap, and coupling/blocking cap in the PA cage and the big choke is not hurt and the parasitic suppressors have good soldering then you should have good anode voltage at the plate caps.

If you are certain that you had resting plate current with no 6146 Anode voltage you had to have Screen Grid voltage. Never good to run screen grids without the anode energized as resulting screen grid current can exceed the screen grid dissipation of the tube. None of this aligns with your report that you had no cathode voltage. Have to have cathode voltage if you had resting plate current. For meter to indicate in IP position have to have IR drop across the cathode meter shunt resistors.

You may have damaged 6146 finals if you truly had no Anode voltage which would be the case with no small vhf choke at base of big choke.

Before installing another set of finals you may want to pull these and leave out and measure the operating bias and screen grid voltage at the tube socket pins. If good then

make sure have anode voltage at top of the plate choke. Have to be very careful with the anode caps dangling in the air. If all voltages available then can install new tubes or try the ones you pulled.

Ron:

I may be a little hard on you.

The actual as built is the 900vdc leaves the HV Rect board on a short red jumper to the HV metering board. From there it leaves on a HV cable that looks like the center of piece of coax and runs to the black terminal strip in the PA cage and on to the small VHF choke and main RF choke.

So I guess it is possible that you might think that if you had no 900vdc anode voltage that the problem could be on that HV metering and SG divider board.

I would not reach for that as I know the voltage is derived from the voltage doubler rectifiers that are on the HV Rect board.

So when I said the 900vdc directly goes from HV Rect board 800 terminal post to the Plate choke that is not technically correct. It goes to the HV metering board and from there on to the PA cage.

As long as you are not blowing the primary fuse focus your efforts on the Anode supply path and not the HV metering board. You of course will need to replace the bad 680k resistors and the bypass cap and do a very good visual to ensure no carbon tracks on this board.

I sure hope you have not applied 900vdc to your panel meter. Will cross that bridge when you find why you have no 6146 anode voltage.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com mailto:TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK the 900vdc does not come out the top of the 6146 finals. The 900vdc is applied there.

You can start measuring in the PA cage and work back to the HV rect board or work the other way. In either case you must observe good safe work practice measuring this 900vdc.

If you have little experience or rusty I suggest you connect the DMM or VTVM first and then power on the rig to take the measurements.

You can also do a good visual inspection with rig unplugged and HV caps discharged.

Visual includes:
1. Is large RF choke in PA cage burned black or any signs of over heating?
2. Is the small VHF choke at base of large choke burned?
3. Is the RF bypass cap at base of large choke burned or blown open
4. Are the rupture vents on the two HV filter caps blown or leaking tar like or dry white powdery deposits. Vents can also be bulged out.

Voltage measurement:
1. Connect the ground lead of your volt meter to the chassis ground post
2. Connect the plus meter lead probe thru a good jumper test lead to the end of parasitic chokes that feed the anode caps.
3. Make sure the end of the jumper lead to your meters plus probe is covered so you cannot make accidental contact.
4. Power on the rig and record the voltage
5. Down power the rig and make sure voltmeter reads zero and then remove the test jumper.
6. Move to the bottom of the large plate choke and connect the test jumper
7. Place self in clear and re-power the rig.
8. Repeat this process all the way back to the HV rectifier board.

Very easy but must be aware of hazards and control your test leads.

Some say put one hand in pocket and that sounds good but not a real practical approach as need free hand to hold flashlite, change meter range etc.

Safest it to connect meter and then put self completely in clear and power on rig and record the voltage and then down power. Must make sure have good positive mechanical connection that wont pop off and must have the probe and test lead interface covered so you dont forget and accidently contact it.

Not trying to insult you. You can move probe from point to point using the meter test prod with rig powered if you are experienced, but still must be constantly aware of what you are doing so you dont slip off or bridge things.

Even today after all these years when I am dealing with anode voltage in an RF amp PA or HV power supply I connect the voltmeter with unit down powered and put myself in safe position and then power on to get the reading. Want to live another day to play!

Ron:

Nothing to be sorry about. I am trying to understand your thought process.

You can throw that disc cap over your shoulder and radio will work fine. How did you determine it was open? This low a value cap you will need a VOM or VTVM and if you blink you can miss the very brief meter flick on the resistance range.

Other way to check it is lift the ground end and connect your VTVM to the free end and set VTVM on lowest DC voltage scale and power on rig and watch for the very brief dc voltage kick. If you get no kick then cap is open and if constant low value of dc then cap is leaky.

If the 680k string was shorted or carbon track to mid point of the divider then you could have applied 900vdc to this cap and to your panel meter. This is why anytime you use this method of measuring HV you use a string of series resistors instead of just one resistor. Not likely for the entire string to short or track across.

Does your panel meter work in RX mode for S-meter indication? If not report back and can tell you how to test your meter.

As to no cathode voltage on the 6146 Finals you must have the rig keyed and dc current flowing to have any voltage on the 6146 cathodes. Need good cathode meter shunt resistors to complete the path and proper operating bias on the control grids and proper screen grid voltage and heaters on.

Can you set the resting or zero signal plate current to 60ma? If so, then you will have cathode voltage.

> If you measured the Cathode voltage at Pin 1 with finals in the socket and rig keyed you

would have to have open cathode resistors or bad ground to see cathode voltage of 15vdc or more. Any time the cathode is lifted from ground it will try to rise toward screen grid voltage (typically over 100 vdc). If you are using a DMM you are completing the path from cathode to ground with the meter so the voltage will drop down once you connect the meter. With rig down powered and unplugged measure the resistance from Pin 1 to ground and should see approx 5 ohms.

>
>
>
> If you measured the Cathode voltage at Pin 1 with finals in the socket and rig keyed you would have to have open cathode resistors or bad ground to see cathode voltage of 15vdc or

more. Any time the cathode is lifted from ground it will try to rise toward screen grid voltage (typically over 100 vdc). If you are using a DMM you are completing the path from cathode to ground with the meter so the voltage will drop down once you connect the meter. With rig down powered and unplugged measure the resistance from Pin 1 to ground and should see approx 5 ohms.
>
>

Subject: [TS-520_820_530_830] RE: Relay transistor question

Terry,

Ok thanks that's what I thought but I wanted to double check. a couple more questions while Im looking at the schematic, The pins on the FIX VOX board are labeled but some Im not sure of their meanings, Ill stick to the ones we've discussed and the few others attached to the relay circuit. The 14A, not sure about the A, SS, VS, and TO. Also the block diagram has a line drawn from Q5 to Q7 but I don't see any connection on the schematic. and Q7, Q8 are labeled what looks like the word SHUMIT on the block diagram, some letters are hard to read, and Q9 is labeled RL CONT. I think RL stands for Relay but im not sure about the cont.

Thanks again,

Daniel

> Not quite correct. The disc ceramic cap is a "2H" which is a 500 wvdc cap.

So, once again, correct me if I'm wrong here. Had he put a 0.01 microFarad, 2000 WVDC ceramic capacitor in the circuit, it would have worked just fine, filtered out the ripple (if any), and not even remotely been a candidate for blowing from over-voltage, nichts wahr?

Erring on the other side, however, is a good way to find out just how tasty the insides of one of these little devils might be.

The process went thusly:

I looked at the meter divider circuit, and noted the nominally ~900 VDC source supply that is being sampled for the meter to measure. Then I rounded it up to the nearest decade (1000 VDC), then I doubled it to get 2000 WVDC. I got into the habit a long time ago of giving myself some HUGE fudge factors, whenever possible, when I was at all uncertain of something. Doubling the voltage was the result of that habit. It wasn't my radio, and it wasn't my face at risk of being peppered and tattooed by bits of exploding capacitor, so the 2000 WVDC rating sounded appropriately cautious.

Then as a check, I looked at the table of parts in the Service manual, and tried to figure out just which one of the excessively-cryptic charts applied to C-1 of that meter sensing board. I took a stab at it and got the 1.8kV working voltage, which oddly enough was rather close to that 2kV guesstimate-with-excessive-fudge-factor figure, and exactly twice the nominal 900 VDC that is expected there from the diode voltage doublers.

PLUS I tossed in the bits about "Please correct me if ..."

So, thanks for the correction. Now I have to go back to that parts list and see if I can make it come out to a 500 WVDC selection, and figure out how I got the wrong (1.8kV) line instead.

(Now, my odd path here takes me from engineering school, but in the 70's, sorry, not the 60's. My career in engineering was about the same as yours, Terry. Most math I can cope with if I'm allowed enough time and access to a textbook or two, but my Achille's Heel was differentials. It got down-right embarrassing.

So I dropped out. Foolish me. There I went, young and stupid, strong back and a half-disciplined mind, they got me when I was at a low point. I wound up in the USAF working for "No Such Agency," speaking Russian, and some German.

I'd give out with the German, and broken Russian, to the Russians, and Russian, and broken German to the Germans. (Yes, that's none of it a typo, I know I did it the right way around since I didn't wind up shot or on the front page.) And took LOTS of pictures.

And on those rare good days, I spoke as little as I could manage of either to anyone. And I spoke American English to NOBODY AT ALL, good day or bad! (English would have made the best day instantly become the worst possible. People in some places get really stuffy and mean about that kind of thing.) And took even MORE photos.

Later, after getting at least a little smarter and getting away with telling the spooks to cut me loose, instead of management they put me where I could do at least some good while still getting my hands dirty, in repair and troubleshooting. I like digging up answers, though I'm quite rusty at the component level now. And then I got a discharge and went home. In almost one large piece, with only a few minor bits missing that nobody will ever miss (except me and I already know I don't count).

Between then and now, it's a free-for-all. I've pulled wire for all kinds of things in construction, bossed a pizza delivery joint, run a Boy Scout camp program, and sold everything from car radio speakers and other Tandy/Radio Shack crapola, to K-band satellite television installations, to installing automation systems in pelletizing feed mills. I did anything I could turn my hand to, to keep my kids fed.

Once I wound up at the University here, I stopped moving around so much. Since then, I have spent a few decades (since ca. the 1990's) working mostly at the board level, and this was in computers instead of radios.

Not a lot of repairs at the component level in a PC or a Macintosh. Or an Irix, SPARCStation, SGI Indy, or what-have-you. Some, and I did what I could when I could, but mostly you just swap a board. Sad business, that.

There. A Nut case, in a Nut shell, by a Nut job. Can't ask for more than that, eh what, mate?

Wes

I am pretty sure I said if he had a 1.8kv wvdc cap in junk box of course it would work just fine..

The flaw I see in your logic is it has nothing to do with 900vdc. The cap is not connected to 900vdc. It is connected to a maximum of 44.0 vdc.

Meter string is 680k x 3 = 2,040,000 /100,000 = 20.4 to 1 voltage ratio. So 900/20.4 = 44.12 vdc. This cap is filtering a nominal 50 vdc supply and not a 900vdc supply.

No manufacturer is going to install a 1.8kv wvdc cap in a circuit where that cap sees voltage under 50v. Closest standard cap would be a 50wvdc. So I would say that when they used a 10x multiplier to spec a 500wvdc cap that they added plenty of margin.

Two groups design and build radios (all commercial products) Engineers and Bean Counters. All good design engineering takes production costs into account. When mass producing even 10 cents per unit cost means something. When the computers came on the scene and replaced the old design Rules of Thumb manufacturing cost went down and we consumers might argue so did quality.

Erring on the other side, however, is a good way to find out just how
tasty the insides of one of these little devils might be.

The process went thusly:

I looked at the meter divider circuit, and noted the nominally ~900 VDC
source supply that is being sampled for the meter to measure. Then I
rounded it up to the nearest decade (1000 VDC), then I doubled it to get
2000 WVDC. I got into the habit a long time ago of giving myself some
HUGE fudge factors, whenever possible, when I was at all uncertain of
something. Doubling the voltage was the result of that habit. It
wasn't my radio, and it wasn't my face at risk of being peppered and
tattooed by bits of exploding capacitor, so the 2000 WVDC rating sounded
appropriately cautious.

Then as a check, I looked at the table of parts in the Service manual, and tried to figure out just which one of the excessively-cryptic charts applied to C-1 of that meter sensing board. I took a stab at it and got the 1.8kV working voltage, which oddly enough was rather close to that 2kV guesstimate-with-excessive-fudge-factor figure, and exactly twice the nominal 900 VDC that is expected there from the diode voltage doublers.

PLUS I tossed in the bits about "Please correct me if ..."

So, thanks for the correction. Now I have to go back to that parts list and see if I can make it come out to a 500 WVDC selection, and figure out how I got the wrong (1.8kV) line instead.

(Now, my odd path here takes me from engineering school, but in the 70's, sorry, not the 60's. My career in engineering was about the same as yours, Terry. Most math I can cope with if I'm allowed enough time and access to a textbook or two, but my Achille's Heel was differentials. It got down-right embarrassing.

So I dropped out. Foolish me. There I went, young and stupid, strong back and a half-disciplined mind, they got me when I was at a low point. I wound up in the USAF working for "No Such Agency," speaking Russian, and some German.

I'd give out with the German, and broken Russian, to the Russians, and Russian, and broken German to the Germans. (Yes, that's none of it a typo, I know I did it the right way around since I didn't wind up shot or on the front page.) And took LOTS of pictures.

And on those rare good days, I spoke as little as I could manage of either to anyone. And I spoke American English to NOBODY AT ALL, good day or bad! (English would have made the best day instantly become the worst possible. People in some places get really stuffy and mean about that kind of thing.) And took even MORE photos.

Later, after getting at least a little smarter and getting away with telling the spooks to cut me loose, instead of management they put me where I could do at least some good while still getting my hands dirty, in repair and troubleshooting. I like digging up answers, though I'm quite rusty at the component level now. And then I got a discharge and went home. In almost one large piece, with only a few minor bits missing that nobody will ever miss (except me and I already know I don't count).

Between then and now, it's a free-for-all. I've pulled wire for all kinds of things in construction, bossed a pizza delivery joint, run a Boy Scout camp program, and sold everything from car radio speakers and other Tandy/Radio Shack crapola, to K-band satellite television installations, to installing automation systems in pelletizing feed mills. I did anything I could turn my hand to, to keep my kids fed.

Once I wound up at the University here, I stopped moving around so much. Since then, I have spent a few decades (since ca. the 1990's) working

mostly at the board level, and this was in computers instead of radios.

Not a lot of repairs at the component level in a PC or a Macintosh. Or an Irix, SPARCStation, SGI Indy, or what-have-you. Some, and I did what I could when I could, but mostly you just swap a board. Sad business, that.

There. A Nut case, in a Nut shell, by a Nut job. Can't ask for more than that, eh what, mate?

Is that measured at RF board? If so, you know problem is between RF board and Tube socket pins.

Ron:

Your note is a bit cryptic.

I thought you had bad meter string resistors or possible carbon path. Did you repair meter board before energizing the rig? If not sure would not put meter in HV position.

Are you saying that when you key the rig in SSB mode with mic gain turned down and the meter in Ip position that you cannot adjust the resting plate current below 230ma with the bias voltage adjust pot run thru its range?

Did you measure the operating bias voltage on the Pin 5 control grids? If operating bias voltage is not correct can cause high resting plate current. Should be approx -55vdc with rig keyed. You should be able to set the bias voltage to -55vdc with the bias voltage adjust pot on side of rig. If you cannot you need to check -C.

Give me more detail on when you are seeing this 230ma IP. You do not want to leave standing 230ma on the finals for more than a few seconds.

If you removed the two 6146 final tubes there would be no reason to measure the cathode voltage at Pin 1. You should not expect any cathode voltage with no tube in the socket?

If you measured the Cathode voltage at Pin 1 with finals in the socket and rig keyed you would have to have open cathode resistors or bad ground to see cathode voltage of 15vdc or more. Any time the cathode is lifted from ground it will try to rise toward screen grid voltage (typically over 100 vdc). If you are using a DMM you are completing the path from cathode to ground with the meter so the voltage will drop down once you connect the meter. With rig down powered and unplugged measure the resistance from Pin 1 to ground and should see approx 5 ohms.

I told you to measure the screen grid voltage and operating bias voltage with tubes removed. You do that with rig keyed in CW mode and SG switch on. I did this so you would not damage tubes again if you had no operating bias. If you dont have bias the tubes will go into thermal runaway.

Terry , the meter indicated a resting bias and I adjusted it to 60ma after doing the repairs to pa cage the meter is resting at 230 ma I removed the finals then measured the pin voltage 15 vdc falling to 3vdc on pin 1 of final. V1 also before repairing the pa cage there was speaker noise now there is none I don't know if this is relevant or not . I can adjust bias up but not down now thanks

Ron KK4PWF

On Nov 5, 2013, at 3:59 PM, <wagstw46@... mailto:wagstw46@...> wrote:

OK Ron....If you have replaced the small choke, bypass cap, and coupling/blocking cap in the PA cage and the big choke is not hurt and the parasitic suppressors have good soldering then you should have good anode voltage at the plate caps.

If you are certain that you had resting plate current with no 6146 Anode voltage you had to have Screen Grid voltage. Never good to run screen grids without the anode energized as resulting screen grid current can exceed the screen grid dissipation of the tube. None of this aligns with your report that you had no cathode voltage. Have to have cathode voltage if you had resting plate current. For meter to indicate in IP position have to have IR drop across the cathode meter shunt resistors.

You may have damaged 6146 finals if you truly had no Anode voltage which would be the case with no small vhf choke at base of big choke.

Before installing another set of finals you may want to pull these and leave out and measure the operating bias and screen grid voltage at the tube socket pins. If good then make sure have anode voltage at top of the plate choke. Have to be very careful with the anode caps dangling in the air. If all voltages available then can install new tubes or try the ones you pulled.

Ron:

I may be a little hard on you.

The actual as built is the 900vdc leaves the HV Rect board on a short red jumper to the HV metering board. From there it leaves on a HV cable that looks like the center of piece of coax and runs to the black terminal strip in the PA cage and on to the small VHF choke and main RF choke.

So I guess it is possible that you might think that if you had no 900vdc anode voltage that the problem could be on that HV metering and SG divider board.

I would not reach for that as I know the voltage is derived from the voltage doubler rectifiers that are on the HV Rect board.

So when I said the 900vdc directly goes from HV Rect board 800 terminal post to the Plate choke that is not technically correct. It goes to the HV metering board and from there on to the PA cage.

As long as you are not blowing the primary fuse focus your efforts on the Anode supply path and not the HV metering board. You of course will need to replace the bad 680k resistors and the bypass cap and do a very good visual to ensure no carbon tracks on this board.

I sure hope you have not applied 900vdc to your panel meter. Will cross that bridge when you find why you have no 6146 anode voltage.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com mailto:TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK the 900vdc does not come out the top of the 6146 finals. The 900vdc is applied there.

You can start measuring in the PA cage and work back to the HV rect board or work the other way. In either case you must observe good safe work practice measuring this 900vdc.

If you have little experience or rusty I suggest you connect the DMM or VTVM first and then power on the rig to take the measurements.

You can also do a good visual inspection with rig unplugged and HV caps discharged.

Visual includes:
1. Is large RF choke in PA cage burned black or any signs of over heating?
2. Is the small VHF choke at base of large choke burned?
3. Is the RF bypass cap at base of large choke burned or blown open
4. Are the rupture vents on the two HV filter caps blown or leaking tar like or dry white powdery deposits. Vents can also be bulged out.

Voltage measurement:
1. Connect the ground lead of your volt meter to the chassis ground post
2. Connect the plus meter lead probe thru a good jumper test lead to the end of parasitic chokes that feed the anode caps.
3. Make sure the end of the jumper lead to your meters plus probe is covered so you cannot make accidental contact.
4. Power on the rig and record the voltage
5. Down power the rig and make sure voltmeter reads zero and then remove the test jumper.
6. Move to the bottom of the large plate choke and connect the test jumper
7. Place self in clear and re-power the rig.

8. Repeat this process all the way back to the HV rectifier board.

Very easy but must be aware of hazards and control your test leads.

Some say put one hand in pocket and that sounds good but not a real practical approach as need free hand to hold flashlite, change meter range etc.

Safest it to connect meter and then put self completely in clear and power on rig and record the voltage and then down power. Must make sure have good positive mechanical connection that wont pop off and must have the probe and test lead interface covered so you dont forget and accidently contact it.

Not trying to insult you. You can move probe from point to point using the meter test prod with rig powered if you are experienced, but still must be constantly aware of what you are doing so you dont slip off or bridge things.

Even today after all these years when I am dealing with anode voltage in an RF amp PA or HV power supply I connect the voltmeter with unit down powered and put myself in safe position and then power on to get the reading. Want to live another day to play!

Ron:

Nothing to be sorry about. I am trying to understand your thought process.

You can throw that disc cap over your shoulder and radio will work fine. How did you determine it was open? This low a value cap you will need a VOM or VTVM and if you blink you can miss the very brief meter flick on the resistance range.

Other way to check it is lift the ground end and connect your VTVM to the free end and set VTVM on lowest DC voltage scale and power on rig and watch for the very brief dc voltage kick. If you get no kick then cap is open and if constant low value of dc then cap is leaky.

If the 680k string was shorted or carbon track to mid point of the divider then you could have applied 900vdc to this cap and to your panel meter. This is why anytime you use this method of measuring HV you use a string of series resistors instead of just one resistor. Not likely for the entire string to short or track across.

Does your panel meter work in RX mode for S-meter indication? If not report back and can tell you how to test your meter.

As to no cathode voltage on the 6146 Finals you must have the rig keyed and dc current flowing to have any voltage on the 6146 cathodes. Need good cathode meter shunt resistors to complete the path and proper operating bias on the control grids and proper screen grid voltage and heaters on.

Can you set the resting or zero signal plate current to 60ma? If so, then you will have cathode voltage.

Ron:

There is some real confusion going on here. I did not tell you to measure the cathode with the tubes removed? Why are you doing that? Should not have any expectation to find any voltage there. I told you to measure the operating bias on the control grids and the screen grid voltage to confirm that it is normal and OK to install another set of finals.

You should not measure any voltage on Pin 1 with tubes pulled.

You cannot measure Infinity from Pin 1 to chassis ground if you have 230ma resting plate current. Cathode circuit cannot be open. Cold end of cathode resistors are connected to heavy solder lugs punched from the chassis at each end of tube sockets. From Pin 1 to ground should measure close to 5 ohms if new resistors and can be approaching 7 ohms for old ones or even higher.

The -80vdc at Pin 1 that you are measuring and reporting sounds close to normal Cut Off bias that you should measure on Pin 5 in Rx mode. Unless someone has completely rewired the tube sockets this makes no sense.

Ron I am afraid I am confused and not helping you very much.

Maybe should close this thread and start a new one and perhaps Mike W5RKL who has lots of TS520 experience can jump in and help you.

Dan

You are asking basic schematic reading questions and KW hybrid abbreviations and conventions. There is no complete list of abbreviations. You can search them out in all the hybrid service manuals. There are various charts in the various manuals.

Some you have to figure out by studying the schematic and some are just common sense. SS for example would be Send Switch. RL CONT is Relay Control because Q9 is configured as a switch that controls the on off cycling of the TR and Aux relay closing coils.

The heavy dashed lines you see on the schematic are control signal lines. If you look at the legend at top of TS820 main schematic you will see this. It means the lead leaves the board and goes to a control and in this case the VOX delay pot.

You can Google on how to read Schematics and find numerous primers and tutorials.

Lastly in this case "SHUNIT" on block diagram is most likely a translation error for Schmitt. With time and experience you should start to recognize some common configurations like Schmitt triggers, Differential amps, Ring diode modulators , Mosfet Doubly Balanced Modulators etc. when you see them on the schematic.

Dan:

I assume you are still experiencing the TR and AUX relays randomly keying when your TS-820 is in Rx mode. Does it do this in all modes? Have you tried it in CW mode? If not do so.

Dirty Anti-Vox pot can be a problem, but not easy to access and clean on the 820.

Let me know if it does it in all modes.

Have you removed and cleaned and re-inserted the FIX2 and FIX3 Molex connectors on the FIX board? If not try that.

If that does not help then can try placing a temporary ground on VS at Molex Conn FIX 3 Pin 2. Make absolutely sure you are on the VS pin. If this works then bad wire or bad/dirty contact at VOX switch not picking up chassis ground.

Trying to rule out noise first before saying there is problem with Q7/Q8. If had O-scope could start by looking at TO line (base of Q7).

Would like to be able to see you at least be able to use the rig in Rx mode.

Terry,
Yes I am still experiencing Relay cycling in Rx ad yes it happens on CW. I have already cleaned all the connectors that I can get too and feel comfortable removing. I also tried grounding the VS and no change either. I took some voltage measurements at the molex connectors with my VTVM today, TO = 5.2vdc, 9 = 9vdc, VS = 0, SS = 14v buts it's unstable and varies +/- 1v when relays cycle, RL = 0 volts when I hear it receiving (you can hear CW when the relays aren't cycling) but it also unstable when the relays do cycle and jumps to between 9-11 vdc, the 14A = 13.9vdc. I also tried attaching a jumper to the base and emitter of Q7, and no change. Getting it working in receive is my main goal for now, I don't have a license yet, but I would like to listen to some chatter, help me learn CW and just have fun. Thanks Terry

So after learning the heater tip from Terry, I took a look at the SM & I also found it there. But when I went to do it last nite, flipping the send switch would pin the ALC meter. I musta worked on that issue while I slept because I told myself in the AM to look at that ground connection that broke when I tried to remove the panel ground screw and darned if I didn't find that the carrier control ground was also broken. There is such a mass of wires there, it is hard to see let alone work in that area. So I fixed that & was able to back off the carrier and the drive section alignment went well. Everything was pretty close already. A good sign.

I also checked the reference oscillator & it was very close to the 10MHz. I spot checked a few other frequency test points and made a few tweaks, but again, there were pretty close. Measurement error probably.

I then tackled the neutralization. This was another scary thing as it was the first time in my short Ham career. Remember: First do no harm. I found it to be pretty close also. I had my scope on 5mV/div and the signal P-P was still pretty small. But I tweaked it a bit lower. Done!

Then I started checking the output on all bands. I found that this 830 would put out 80 -115W on all bands but 18MHz, where I could only get ~20W. So I went back to 18MHz after I completing 29MHz and I got ~95W on the 2nd try. So either my technique got better or …..? Could a dirty band switch do that? Any other thoughts? I also find that the load control on some bands is at or near it's stop Typical? 73 - Bob

Bob,

  Nice job!

Quite possible that the low power on 18Mhz was caused by "dirty" band switch wafer contacts.
This is common...especially for a rig that may have sat for lord knows how long. Continue to monitor that situation. Maybe a good cleaning with your choice of contact cleaner/lube and a good blow off with canned air. Follow the directions...that stuff is flammable...use with rig OFF...and preferably UNPLUGGED,,,but that's just me

  Neutralization can make one nervous...at first..as....ya don't want to blow it up...but you did right, by reading the directions..and following(I hope) safety precautions. As you found out...your chances of getting a complete zero reading on your o'scope or DMM/VTVM is not always possible....adjust for the lowest possible reading/dip.

  Having the "load" control "at or near the top" is fine.(.using a dummy load..I hope)

   When using an "actual" antenna...as to paraphrase... "your actual readings/settings may vary."

Ron:

I put the K12 in both of my TS-830 and did not notice dramatic difference but maybe I do not have a discriminating ear.

I dont have a spectrum analyzer to do any precise alignments but I have swept both filters on the bench terminated with 2k ohm input/output and I found the K5 to be close to 2.4khz @6dB BW and the K12 close to 2.9khz @ 6db BW.

If you can pick them up for $40 to $50 probable worth a try.

Here is spectrum analyzer look at a K12 filter installed in a FT-1000.

I did not refer you to the Service Manual as it requires good calibrated RF sig gen to perform RF/IF and Coil Pack alignment that precedes the Drive Coil alignment.

Average ham with no or limited test gear can do pretty decent job by following the procedures in the Maintenance Section of the Operating Manual.

That is why the maintenance section exists in that manual. It details owner/operator adjustments that can put rig in decent state of tune that does not require any test gear or tech knowledge or experience.

Had I known you had good RF bench I would have referred you to the Service Manual. It helps when new folks give brief biography and tell what test gear they have. I should have asked.

OK it looks like you have done everything that you can. SS would normally be 14vdc in Rx mode and when you flip to Send it should go to zero.

If running VOX SS will be approx 14vdc and when you speak in mic and key the relays with audio SS will drop from approx 14vdc to approx 11vdc. So normal for SS to be dropping when the relays are cycling.

I think time to contact Bob Mansker and see if he has a FIX board.

If you want to use rig as receiver in mean time should be able to unplug FIX-3 Molex conn.

Yes I am still experiencing Relay cycling in Rx ad yes it happens on CW. I have already cleaned all the connectors that I can get too and feel comfortable removing. I also tried grounding the VS and no change either. I took some voltage measurements at the molex connectors with my VTVM today, TO = 5.2vdc, 9 = 9vdc, VS = 0, SS = 14v buts it's unstable and varies +/- 1v when relays cycle, RL = 0 volts when I hear it receiving (you can hear CW when the relays aren't cycling) but it also unstable when the relays do cycle and jumps to between 9-11 vdc, the 14A = 13.9vdc. I also tried attaching a jumper to the base and emitter of Q7, and no change. Getting it working in receive is my main goal for now, I don't have a license yet, but I would like to listen to some chatter, help me learn CW and just have fun. Thanks Terry

Dan:

I assume you are still experiencing the TR and AUX relays randomly keying when your TS-820 is in Rx mode. Does it do this in all modes? Have you tried it in CW mode? If not do so.

Dirty Anti-Vox pot can be a problem, but not easy to access and clean on the 820.

Let me know if it does it in all modes.

Have you removed and cleaned and re-inserted the FIX2 and FIX3 Molex connectors on the FIX board? If not try that.

If that does not help then can try placing a temporary ground on VS at Molex Conn FIX 3 Pin 2. Make absolutely sure you are on the VS pin. If this works then bad wire or bad/dirty contact at VOX switch not picking up chassis ground.

Trying to rule out noise first before saying there is problem with Q7/Q8. If had O-scope could start by looking at TO line (base of Q7).

Would like to be able to see you at least be able to use the rig in Rx mode.

You are asking basic schematic reading questions and KW hybrid abbreviations and conventions. There is no complete list of abbreviations. You can search them out in all the hybrid service manuals. There are various charts in the various manuals.

Some you have to figure out by studying the schematic and some are just common sense. SS for example would be Send Switch. RL CONT is Relay Control because Q9 is configured as a switch that controls the on off cycling of the TR and Aux relay closing coils.

The heavy dashed lines you see on the schematic are control signal lines. If you look at the legend at top of TS820 main schematic you will see this. It means the lead leaves the board and goes to a control and in this case the VOX delay pot.

You can Google on how to read Schematics and find numerous primers and tutorials.

Lastly in this case "SHUNIT" on block diagram is most likely a translation error for Schmitt. With time and experience you should start to recognize some common configurations like Schmitt triggers, Differential amps, Ring diode modulators , Mosfet Doubly Balanced Modulators etc. when you see them on the schematic.

Terry, I tried unplugging Molex conn 3 and there was no receive then. Is there any reason to put a jumper from base to emitter on Q8 or Q9? I didn't get much reading done on the Schmidt trigger circuit today, hoping for more time tomorrow. I'm only wondering cause a transistor swap would be better for me financially (no job) then a whole board. Thanks

Daniel

Hi Terry,

Thanks for the info and the link. I had a K-12 here so I went ahead and put it in one of my TS-830's. When I compare the rigs side by side with the same speakers
I would say that the one with the cf-12 has a little bit better fidelity. Not a huge difference but it
is a difference. I guess every little bit helps. I don't think it is a must have modification.
Thanks again for your reply,

Ron WD9IQN

OK Ron that is good way to do it if you have two rigs.

I have found over years that a lot of these upgrades and mods produce "feel good" results. Much is subjective. So few really have the test gear or the knowledge to do meaningful before and after testing to measure the improvements and some will be very slight.

I guess if it makes your ears happy all that matters. Accept for those who think that 6khz + wide SSB signals sound good!

One thing that I always come back to is the receive audio quality of the old TS520 versus the TS-830. To my ears the old complementary pair OTL audio amp circuit produces much better audio than the integrated chip audio output circuit of the TS830.

Anyway, enjoy your TS830s

73s Terry K9TW

OK sorry about that . I did a quick look and didnt see a problem pulling the connector.

What you are doing when you jumper from Base to Emitter is turning the transistor off. When you do that should monitor Collector voltage and if the transistor was on then the Collector voltage should move up toward supply voltage. This is a standard in circuit transistor troubleshooting test but must be 100% sure you are on the B-E leads.

Other standard test is to place a 10K ohm resistor in series with your test jumper and jump from Base to Collector while monitoring Collector voltage. This test you are biasing on the transistor and if collector voltage drops then you know device has turned on.

Normally if you can turn on or turn off a transistor it is good. However, the test doesnt tell you anything about leakage or how well the transistor will amplify or oscillate especially at RF frequencies, but a pretty good test to find a shorted or open transistor.

I suggested turning off Q7 to see if noise at the input was the source of the problem. Schmitt trigger should have upper and lower thresholds and noise filtered out by the hysteresis loop should not trigger an output. Need a O-scope to look at Base of Q7 to see if noise is the issue.

I understand if you have limited funds you would prefer to troubleshoot and repair the board.

Perhaps Q9 is just leaky? It sees a lot of cycles and may simply be leaky.

I guess at this point you can order subs for Q7, Q8 and Q9 and try replacing all three while you have the board out. Would prefer to troubleshoot to id the problem but given age of rig and difficulty troubleshooting via long distance OK to just replace all three of them. If you do that also replace D17 while board is out.

Best I can do for you and perhaps someone else would have a suggestion to help you.

Dan:

Took another look and see that -6vdc is produced by T-powered supply on the FIX board so you can pull FIX3 and use a 6vdc lantern battery to power -6vdc bus. Plus lead of battery to chassis ground. Very little current so cheap Dollar Store 6 vdc battery will last long time.

The heavy dashed lines you see on the schematic are control signal lines. If you look at the legend at top of TS820 main schematic you will see this. It means the lead leaves the board and goes to a control and in this case the VOX delay pot.

You can Google on how to read Schematics and find numerous primers and tutorials.

Lastly in this case "SHUNIT" on block diagram is most likely a translation error for Schmitt. With time and experience you should start to recognize some common configurations like Schmitt triggers, Differential amps, Ring diode modulators , Mosfet Doubly Balanced Modulators etc. when you see them on the schematic.

Hi Joe & Terry, et al,

I made my own dummy load. Bunch of 5 watters sitting in mineral oil. It measures 50.4ohms. And I have a scope, several generators, dvms, FETVOM's, EICO tube tester, ESR meter, ... ie- more test equipment than sense/knowledge. But I don't have a good sweeper (I don't think). I need a good vulcan mind transfer to enable full utilization on all the junk I got.

I will look at the band switches & clean them & try to remember to unplug the unit while doing so. I try to unplug the devise I am working on once I am done with it for the day. I have had too many mistakes. Unencumbered by the thought process, so to speak.

I may put it on the air today. I found an old Turner +3 to stick on it.

Thanx for all the continued help. - Bob

---In TS-520_820_530_830@yahoogroups.com, <stilesjoseph@...> wrote:

Bob,

Nice job!

Quite possible that the low power on 18Mhz was caused by "dirty" band switch wafer contacts.
This is common...especially for a rig that may have sat for lord knows how long. Continue to monitor that situation. Maybe a good cleaning with your choice of contact cleaner/lube and a good blow off with canned air. Follow the directions...that stuff is flammable...use with rig OFF...and preferably UNPLUGGED,,,but that's just me

Neutralization can make one nervous...at first..as....ya don't want to blow it up...but you did right, by reading the directions..and following(I hope) safety precautions. As you found out...your chances of getting a complete zero reading on your o'scope or DMM/VTVM is not always possible....adjust for the lowest possible reading/dip.

Having the "load" control "at or near the top" is fine.(.using a dummy load..I hope)

When using an "actual" antenna...as to paraphrase... "your actual readings/settings may vary."

OK Bob:

I think you should find that a good RF Sig Gen is much more useful than a RF sweep gen. A Sweep gen is good for band pass filter alignments, but not first piece of gear would get.

Can use old LC type RF sig gens (Heath, Knight, Eico) and set to high output level as measured by your O-scope and then use external step attenuators to get the accurate low RF output levels you need to inject at various points in the Service Manual alignment steps. It is a little convoluted and most LC types are not very well shielded so not good for very low level signal injection.

These old sig gens are fine for troubleshooting but are not very good for alignments.

Also, remember your RF Sig Gen doesnt use the KW hybrid Japanese dBu levels called out in the Service Manual.

When you are going to use the RF Sig Gen in lieu of the Marker signal to do the Coil Pack alignment you must convert from the KW levels to standard American values. Calculator with Log and Anti-log is handy and can find some calculators and charts on line. I made a conversion chart for common values and have an excel spread sheet. I also marked up the Service manual any place it called out a dBu level.

So if you are going to use your Heath IG-102 to perform TS830 Step 16 Coil Pack Alignment how will you set the output for the required 40dB and -6dB? Might make a good W5RKL test exercise down the road?

As I said can be done but not as easy as with a good PLL based RF sig gen or one of the new DDS RF sig gens.

By the way to check your calcs should find that 40db = -73dBm or 0.50uv and -6dB = -119 dBm or 0.25uv. These are units that a good RF sig gen present directly at the calibrated step attenuator.

Sorry if you already know all of this.

For those that dont and dont have RF bench then I still recommend using the Maintenance Section of their respective KW hybrid manuals to set their TX and RX performance pretty close to factory spec.

Terry, I put a jumper from B to E on Q9 and the relays stop cycling collector voltage stayed at 0v and the radio began receiving great, There are a few problems with 10 and 15 meters but I'm going to enjoy 20 - 160m for now while I read up and wait for some new transistors in the mail. Thank you so much for all your help this has been a great lesson and you've been a great help getting this radio back work. Cant wait to learn more about this radio and electronics.

Took another look and see that -6vdc is produced by T-powered supply on the FIX board so you can pull FIX3 and use a 6vdc lantern battery to power -6vdc bus. Plus lead of battery to chassis ground. Very little current so cheap Dollar Store 6 vdc battery will last long time.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK sorry about that . I did a quick look and didnt see a problem pulling the connector.

What you are doing when you jumper from Base to Emitter is turning the transistor off. When you do that should monitor Collector voltage and if the transistor was on then the Collector voltage should move up toward supply voltage. This is a standard in circuit transistor troubleshooting test but must be 100% sure you are on the B-E leads.

Other standard test is to place a 10K ohm resistor in series with your test jumper and jump from Base to Collector while monitoring Collector voltage. This test you are biasing on the transistor and if collector voltage drops then you know device has turned on.

Normally if you can turn on or turn off a transistor it is good. However, the test doesnt tell you anything about leakage or how well the transistor will amplify or oscillate especially at RF frequencies, but a pretty good test to find a shorted or open transistor.

I suggested turning off Q7 to see if noise at the input was the source of the problem. Schmitt trigger should have upper and lower thresholds and noise filtered out by the hysteresis loop should not trigger an output. Need a O-scope to look at Base of Q7 to see if noise is the issue.

I understand if you have limited funds you would prefer to troubleshoot and repair the board.

Perhaps Q9 is just leaky? It sees a lot of cycles and may simply be leaky.

I guess at this point you can order subs for Q7, Q8 and Q9 and try replacing all three while you have the board out. Would prefer to troubleshoot to id the problem but given age of rig and difficulty troubleshooting via long distance OK to just replace all three of them. If you do that also replace D17 while board is out.

Best I can do for you and perhaps someone else would have a suggestion to help you.

Dan:

I assume you are still experiencing the TR and AUX relays randomly keying when your TS-820 is in Rx mode. Does it do this in all modes? Have you tried it in CW mode? If not do so.

Dirty Anti-Vox pot can be a problem, but not easy to access and clean on the 820.

Let me know if it does it in all modes.

Have you removed and cleaned and re-inserted the FIX2 and FIX3 Molex connectors on the FIX board? If not try that.

If that does not help then can try placing a temporary ground on VS at Molex Conn FIX 3 Pin 2. Make absolutely sure you are on the VS pin. If this works then bad wire or bad/dirty contact at VOX switch not picking up chassis ground.

Trying to rule out noise first before saying there is problem with Q7/Q8. If had O-scope could start by looking at TO line (base of Q7).

Would like to be able to see you at least be able to use the rig in Rx mode.

You are asking basic schematic reading questions and KW hybrid abbreviations and conventions. There is no complete list of abbreviations. You can search them out in all the hybrid service manuals. There are various charts in the various manuals.

Some you have to figure out by studying the schematic and some are just common sense. SS for example would be Send Switch. RL CONT is Relay Control because Q9 is configured as a switch that controls the on off cycling of the TR and Aux relay closing coils.

OK then you have reverse biased the B-E junction and transistor is cut off and will be no voltage at Collector. Still does not tell you what is wrong. By the way the voltages shown on my FIX board schematic at Q9 are wrong . Not 16vdc but closer to 13.8vdc.

If you plan to replace Q9 check on Ebay first for a NOS 2SA562Y before you buy a NTE 290A sub.

OK sorry about that . I did a quick look and didnt see a problem pulling the connector.

What you are doing when you jumper from Base to Emitter is turning the transistor off. When you do that should monitor Collector voltage and if the transistor was on then the Collector voltage should move up toward supply voltage. This is a standard in circuit transistor troubleshooting test but must be 100% sure you are on the B-E leads.

Other standard test is to place a 10K ohm resistor in series with your test jumper and jump from Base to Collector while monitoring Collector voltage. This test you are biasing on the

transistor and if collector voltage drops then you know device has turned on.

Normally if you can turn on or turn off a transistor it is good. However, the test doesnt tell you anything about leakage or how well the transistor will amplify or oscillate especially at RF frequencies, but a pretty good test to find a shorted or open transistor.

I suggested turning off Q7 to see if noise at the input was the source of the problem. Schmitt trigger should have upper and lower thresholds and noise filtered out by the hysteresis loop should not trigger an output. Need a O-scope to look at Base of Q7 to see if noise is the issue.

I understand if you have limited funds you would prefer to troubleshoot and repair the board.

Perhaps Q9 is just leaky? It sees a lot of cycles and may simply be leaky.

I guess at this point you can order subs for Q7, Q8 and Q9 and try replacing all three while you have the board out. Would prefer to troubleshoot to id the problem but given age of rig and difficulty troubleshooting via long distance OK to just replace all three of them. If you do that also replace D17 while board is out.

Best I can do for you and perhaps someone else would have a suggestion to help you.

Dan:

I assume you are still experiencing the TR and AUX relays randomly keying when your TS-820 is in Rx mode. Does it do this in all modes? Have you tried it in CW mode? If not do so.

Dirty Anti-Vox pot can be a problem, but not easy to access and clean on the 820.

Let me know if it does it in all modes.

Have you removed and cleaned and re-inserted the FIX2 and FIX3 Molex connectors on the FIX board? If not try that.

If that does not help then can try placing a temporary ground on VS at Molex Conn FIX 3 Pin 2. Make absolutely sure you are on the VS pin. If this works then bad wire or bad/dirty contact at VOX switch not picking up chassis ground.

Trying to rule out noise first before saying there is problem with Q7/Q8. If had O-scope could start by looking at TO line (base of Q7).

Would like to be able to see you at least be able to use the rig in Rx mode.

You are asking basic schematic reading questions and KW hybrid abbreviations and conventions. There is no complete list of abbreviations. You can search them out in all the hybrid service manuals. There are various charts in the various manuals.

Some you have to figure out by studying the schematic and some are just common sense. SS for example would be Send Switch. RL CONT is Relay Control because Q9 is configured as a switch that controls the on off cycling of the TR and Aux relay closing coils.

The heavy dashed lines you see on the schematic are control signal lines. If you look at the legend at top of TS820 main schematic you will see this. It means the lead leaves the board and goes to a control and in this case the VOX delay pot.

You can Google on how to read Schematics and find numerous primers and tutorials.

Lastly in this case "SHUNIT" on block diagram is most likely a translation error for Schmitt. With time and experience you should start to recognize some common configurations like Schmitt triggers, Differential amps, Ring diode modulators , Mosfet Doubly Balanced Modulators etc. when you see them on the schematic.

TYPO

40db is -73dBm but it is not 0.50uv

It is 50.0 uv (50 micro volts not 1/2 micro volt)

50.0uv will give you S-9 meter indication

Sorry about that

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK Bob:

I think you should find that a good RF Sig Gen is much more useful than a RF sweep gen. A Sweep gen is good for band pass filter alignments, but not first piece of gear would get.

Can use old LC type RF sig gens (Heath, Knight, Eico) and set to high output level as measured by your O-scope and then use external step attenuators to get the accurate low RF output levels you need to inject at various points in the Service Manual alignment steps. It is a little convoluted and most LC types are not very well shielded so not good for very low level signal injection.

These old sig gens are fine for troubleshooting but are not very good for alignments.

Also, remember your RF Sig Gen doesnt use the KW hybrid Japanese dBu levels called out in the Service Manual.

When you are going to use the RF Sig Gen in lieu of the Marker signal to do the Coil Pack alignment you must convert from the KW levels to standard American values. Calculator with Log and Anti-log is handy and can find some calculators and charts on line. I made a conversion chart for common values and have an excel spread sheet. I also marked up the Service manual any place it called out a dBu level.

So if you are going to use your Heath IG-102 to perform TS830 Step 16 Coil Pack Alignment how will you set the output for the required 40dB and -6dB? Might make a good W5RKL test exercise down the road?

As I said can be done but not as easy as with a good PLL based RF sig gen or one of the new DDS RF sig gens.

By the way to check your calcs should find that 40db = -73dBm or 0.50uv and -6dB = -119 dBm or 0.25uv. These are units that a good RF sig gen present directly at the calibrated step attenuator.

Sorry if you already know all of this.

For those that dont and dont have RF bench then I still recommend using the Maintenance Section of their respective KW hybrid manuals to set their TX and RX performance pretty close to factory spec.

Hi Joe & Terry, et al,

I made my own dummy load. Bunch of 5 watters sitting in mineral oil. It measures 50.4ohms. And I have a scope, several generators, dvms, FETVOM's, EICO tube tester, ESR meter, ... ie- more test equipment than sense/knowledge. But I don't have a good sweeper (I don't think). I need a good vulcan mind transfer to enable full utilization on all the junk I got.

I will look at the band switches & clean them & try to remember to unplug the unit while doing so. I try to unplug the devise I am working on once I am done with it for the day. I have had too many mistakes. Unencumbered by the thought process, so to speak.

I may put it on the air today. I found an old Turner +3 to stick on it.

Thanx for all the continued help. - Bob

---In TS-520_820_530_830@yahoogroups.com, <stilesjoseph@...> wrote:

Bob,

Nice job!

Quite possible that the low power on 18Mhz was caused by "dirty" band switch wafer contacts.
This is common...especially for a rig that may have sat for lord knows how long. Continue to monitor that situation. Maybe a good cleaning with your choice of contact cleaner/lube and a good blow off with canned air. Follow the directions...that stuff is flammable...use with rig OFF...and preferably UNPLUGGED,,,but that's just me

Neutralization can make one nervous...at first..as....ya don't want to blow it up...but you did right, by reading the directions..and following(I hope) safety precautions. As you found out...your chances of getting a complete zero reading on your o'scope or DMM/VTVM is not always possible....adjust for the lowest possible reading/dip.

Having the "load" control "at or near the top" is fine.(.using a dummy load..I hope)

When using an "actual" antenna...as to paraphrase... "your actual readings/settings may vary."

So after learning the heater tip from Terry, I took a look at the SM & I also found it there. But when I went to do it last nite, flipping the send switch would pin the ALC meter. I musta worked on that issue while I slept because I told myself in the AM to look

at that ground connection that broke when I tried to remove the panel ground screw and darned if I didn’t find that the carrier control ground was also broken. There is such a mass of wires there, it is hard to see let alone work in that area. So I fixed that & was able to back off the carrier and the drive section alignment went well. Everything was pretty close already. A good sign.

I also checked the reference oscillator & it was very close to the 10MHz. I spot checked a few other frequency test points and made a few tweaks, but again, there were pretty close. Measurement error probably.

I then tackled the neutralization. This was another scary thing as it was the first time in my short Ham career. Remember: First do no harm. I found it to be pretty close also. I had my scope on 5mV/div and the signal P-P was still pretty small. But I tweaked it a bit lower. Done!

Then I started checking the output on all bands. I found that this 830 would put out 80 -115W on all bands but 18MHz, where I could only get ~20W. So I went back to 18MHz after I completing 29MHz and I got ~95W on the 2nd try. So either my technique got better or …..? Could a dirty band switch do that? Any other thoughts? I also find that the load control on some bands is at or near it's stop Typical? 73 - Bob

Daniel

Thinking about your inability to acquire replacement FIX board at this time and wanting to continue working on your TS820 consider this approach:

1. Remove your jumper from Q9
2. Apply B-E jumper at Q7 (be 100% on correct leads) OR try unplugging FIX2 connector to stop the on/off relay keying in Rx mode. Easier than applying B-E jumper.
3. Flip to Send to see if the rig relays can now be keyed on and off by Q9.
4. If this works all you have lost is the VOX function.

This allows you to continue working on the receiver and transmitter. Can come back later and replace transistors on FIX board or swap out FIX boards to restore VOX function.

What you are doing when you jumper from Base to Emitter is turning the transistor off. When you do that should monitor Collector voltage and if the transistor was on then the Collector voltage should move up toward supply voltage. This is a standard in circuit transistor troubleshooting test but must be 100% sure you are on the B-E leads.

Other standard test is to place a 10K ohm resistor in series with your test jumper and jump from Base to Collector while monitoring Collector voltage. This test you are biasing on the transistor and if collector voltage drops then you know device has turned on.

Normally if you can turn on or turn off a transistor it is good. However, the test doesnt tell you anything about leakage or how well the transistor will amplify or oscillate especially at RF frequencies, but a pretty good test to find a shorted or open transistor.

I suggested turning off Q7 to see if noise at the input was the source of the problem. Schmitt trigger should have upper and lower thresholds and noise filtered out by the hysteresis loop should not trigger an output. Need a O-scope to look at Base of Q7 to see if noise is the issue.

I understand if you have limited funds you would prefer to troubleshoot and repair the board.

Perhaps Q9 is just leaky? It sees a lot of cycles and may simply be leaky.

I guess at this point you can order subs for Q7, Q8 and Q9 and try replacing all three while you have the board out. Would prefer to troubleshoot to id the problem but given age of rig and difficulty troubleshooting via long distance OK to just replace all three of them. If you do that also replace D17 while board is out.

Best I can do for you and perhaps someone else would have a suggestion to help you.

Dan:

I assume you are still experiencing the TR and AUX relays randomly keying when your TS-820 is in Rx mode. Does it do this in all modes? Have you tried it in CW mode? If not do so.

Dirty Anti-Vox pot can be a problem, but not easy to access and clean on the 820.

Let me know if it does it in all modes.

Have you removed and cleaned and re-inserted the FIX2 and FIX3 Molex connectors on the FIX board? If not try that.

If that does not help then can try placing a temporary ground on VS at Molex Conn FIX 3 Pin 2. Make absolutely sure you are on the VS pin. If this works then bad wire or bad/dirty contact at VOX switch not picking up chassis ground.

Trying to rule out noise first before saying there is problem with Q7/Q8. If had O-scope could start by looking at TO line (base of Q7).

Would like to be able to see you at least be able to use the rig in Rx mode.

You are asking basic schematic reading questions and KW hybrid abbreviations and conventions. There is no complete list of abbreviations. You can search them out in all the hybrid service manuals. There are various charts in the various manuals.

Some you have to figure out by studying the schematic and some are just common sense. SS for example would be Send Switch. RL CONT is Relay Control because Q9 is configured as a switch that controls the on off cycling of the TR and Aux relay closing coils.

The heavy dashed lines you see on the schematic are control signal lines. If you look at the legend at top of TS820 main schematic you will see this. It means the lead leaves the board and goes to a control and in this case the VOX delay pot.

You can Google on how to read Schematics and find numerous primers and tutorials.

Lastly in this case "SHUNIT" on block diagram is most likely a translation error for Schmitt. With time and experience you should start to recognize some common configurations like Schmitt triggers, Differential amps, Ring diode modulators , Mosfet Doubly Balanced Modulators etc. when you see them on the schematic.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <danweed85@...> wrote:

Terry,

Ok thanks that's what I thought but I wanted to double check. a couple more questions while Im looking at the schematic, The pins on the FIX VOX board are labeled but some Im not sure

of their meanings, Ill stick to the ones we've discussed and the few others attached to the relay circuit. The 14A, not sure about the A, SS, VS, and TO. Also the block diagram has a line drawn from Q5 to Q7 but I don't see any connection on the schematic. and Q7, Q8 are labeled what looks like the word SHUMIT on the block diagram, some letters are hard to read, and Q9 is labeled RL CONT. I think RL stands for Relay but im not sure about the cont.

Thanks again,
Daniel

Daniel

Thinking about your inability to acquire replacement FIX board at this time and wanting to continue working on your TS820 consider this approach:

1. Remove your jumper from Q9
2. Apply B-E jumper at Q7 (be 100% on correct leads) OR try unplugging FIX2 connector to stop the on/off relay keying in Rx mode. Easier than applying B-E jumper.
3. Flip to Send to see if the rig relays can now be keyed on and off by Q9.
4. If this works all you have lost is the VOX function.

This allows you to continue working on the receiver and transmitter. Can come back later and replace transistors on FIX board or swap out FIX boards to restore VOX function.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Daniel

Q9 could be bad but it could also be getting input from the Schmitt trigger. So you can just replace it alone as a first step if you want or replace all three active devices while the board is out. Your choice.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <danweed85@...> wrote:

 Terry, Darn I was hoping that meant a bad transistor. Ive seem them on ebay, ill dig back into it later after im done reading tonight see I can find the exact issue. Thanks again

Daniel

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK then you have reverse biased the B-E junction and transistor is cut off and will be no voltage at Collector. Still does not tell you what is wrong. By the way the voltages shown on my FIX board schematic at Q9 are wrong . Not 16vdc but closer to 13.8vdc.

If you plan to replace Q9 check on Ebay first for a NOS 2SA562Y before you buy a NTE 290A sub.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <danweed85@...> wrote:

Terry, I put a jumper from B to E on Q9 and the relays stop cycling collector voltage stayed at 0v and the radio began receiving great, There are a few problems with 10 and 15 meters but I'm going to enjoy 20 - 160m for now while I read up and wait for some new transistors in the mail. Thank you so much for all your help this has been a great lesson and you've been a great help getting this radio back work. Cant wait to learn more about this radio and electronics.

I was going to correct you... NOT! My limited tolerance for all the conversions puts me at a decided disadvantage to you, Terry. I can do it, but have little energy around it. I still remember 14.53PSI (not 14.7) per Bar, but that is little help here.

I put the old gal on the air last nite! I found I had to turn the IF shift fully clockwise to receive good audio on SSB. Not good. When centered, audio was very pinched. Worse yet, I got horrible audio reports when transmitting. I tried 2 mics, to no avail. On the plus side, it did put out 100+W on 80M while still being below 225mA Ip.

So I disconnected & started the laborious and mentally challenging, because I have trouble with directions, alignment procedure from step 1. Are there any known mistakes? I even found D40 TP3 on the PLL board even tho it isn't marked on the test point layout on pg 43. Getting Carrier L19&20 to level out was a PITB. L19& 20 are very interactive & requires twisted logic to get them close to the 0.3VDC. I also checked the ESR on all the HV electrolytics & they were very good.

So I'll give it a go again tonite & see if I made things worse or better. If worse, look for me on the QRZ SK list. ;-) 73 - Bob

TYPO

40db is -73dBm but it is not 0.50uv

It is 50.0 uv (50 micro volts not 1/2 micro volt)

50.0uv will give you S-9 meter indication

Sorry about that

I don't have 2SA562's in stock, but I have 2SA564's. I think I have about six of them. The are N.O.S. parts.
I have the contents of three electronic service departments that have all gone out of business.
They were in business from 1970's through the year 2001.
Let me know if I can help with other N.O.S. transistors. (CHEAP!)
P/S please don't ask me to make up a list of what I have. (It could take years)

Bob

Any time what I say doesnt make sense or look correct please speak up. It also lets me know someone cares and is reading this stuff. No this was not a test!

Yes L19 and L20 are interactive and not easy until you get the hang of it. I recommend using an O-scope unless you have a good RF millivolt meter that can read 0.30v rms. On the scope you will be adjusting for 0.848 P-P in both LSB and USB. Remember to turn L20 CCW direction.

Plus or minus 1dB tolerance means a high of 337mv and a low of 267mv. This is 0.953 P-P to 0.755 P-P.

I think Gordon N6WK was one of the first in the group to help with this.

Hi Terry,
I am a neophyte here & not likely to correct anyone, because most know more than I do. I did not check your math. Nor have I checked your recent conversion from dB to mV. I know I got them very close to 0.31VDC which was close enough for me. And you just confirmed it was close enough. Know that I read all of your posts.

It has been a great adventure working on this 830. I have had tube receivers (several Hammarlunds) but this is my first Hybrid transceiver. I appreciate the help & patience.

Still looking for an MC50 or if anyone has tried a Heil HM12 on their 830, I'd like to know how it worked out. - 73 Bob

Bob

You cant adjust the 8.830mhz Carrier Osc to 0.31vdc. You adjust it to 0.31vac. Have to use RF probe and VTVM, RF millivolt meter, or an O-scope.

It is an AC signal at RF frequency. Whenever you see RF VTVM listed under the Test Equipment heading it tells you that you are measuring a high frequency AC signal.

Terry K9TW

Any time what I say doesnt make sense or look correct please speak up. It also lets me know someone cares and is reading this stuff. No this was not a test!

Yes L19 and L20 are interactive and not easy until you get the hang of it. I recommend using an O-scope unless you have a good RF millivolt meter that can read 0.30v rms. On the scope you will be adjusting for 0.848 P-P in both LSB and USB. Remember to turn L20 CCW direction.

Plus or minus 1dB tolerance means a high of 337mv and a low of 267mv. This is 0.953 P-P to 0.755 P-P.

I think Gordon N6WK was one of the first in the group to help with this.

From: W5RKL
Topic: 6044 Message: 45796

No problem Ron.

The 520 final amplifier can be easily fixed, rewired back to it's original state. You MUST follow the 520 schematic. Use new 10 ohm 1 watt resistors in the cathode, a new 1/2 watt 3.3K meter multiplier resistors, and new 100 ohm 1/2 watt resistors for the SG circuit.

The pins on the 2 final tube sockets, as viewed from below the chassis, are oriented "clockwise". Look close at each pin on the bottom of the sockets, the pin numbers are usually stamped next to each pin. If you can't see them, look at the center "guide hole", there's a single tab. The tab points between pins 1 and 8. Pin 1 is just to the left of the tab.

A jumper wire must connect pin 1 on the front tube socket to pin 1 on the rear final tube socket. This puts both final tube cathodes in "parallel".

Pin 1 on both sockets should have a 1 watt 10 ohm resistor connected from pin 1 to ground (chassis). The 3.3K 1/2 watt meter multiplier resistors is connected from pin 1 to the tab on the terminal strip then a wire connects that tab to the meter switch "IP" position.

Pin 8 on both final tube sockets is connected to ground. Pin 8 on the final tube connects to the metal ring at the bottom of the 6146s so each of the tube socket's pin 8 is connected to the chassis (ground).

There are "six" .004ufd disc bypass capacitors to ground in the cathode circuit. This results in a total capacitance of .24ufd of cathode bypass capacitance. Bypass capacitors should have short leads to ground (chassis). Long bypass capacitor leads are not an option so make sure the bypass cap leads, when connected between the tube socket pins and ground are as short as possible. You may have to use insulation around the cap leads to prevent shorts.

Each SG tube socket pin 3 has a .01ufd bypass capacitor connected to the chassis.

A 100 ohm 1/2 watt resistor is connected to each socket's pin 3 (SG) and the other leads of the resistors are tied together then a wire connects that junction to the "SG" switch on the rear panel..

Both tube sockets should have a shorting wire connecting pins 1, 4, and 6. Pins 1 and 6 are the cathodes on each tube socket. Pin 4 is the tube socket's connection to the beam forming plates inside the 6146s. The beam forming plates AND the cathode are "negative" in respects to the plate which is what they should be and that's why there's a jumper wire connecting pins 1, 4, and 6 on each tube socket.

Filament voltage for the 6146s, 12VAC, comes from the HEATER switch and connects to pin 2 of the front final tube socket (V1). Pin 7 of V1 final tube socket connects to pin 2 of the rear final tube socket, V2, through a jumper wire. Pin 7 of V2 connects to ground. This completes the filament wiring for both tube sockets. There also should be a wire from pin 2 on V1 that connects to the RF Unit board's "H" terminal. This connection provides 12VAC for the 12BY7 driver tube.

All this wiring is clearly shown on the 520 schematic.

Hi Terry,
I was using a Fluke 82RF HF probe that goes into my Fluke 189 set for DC. According to the specs: 0.25V at 10MHz in =0.25VDC out plus/minus 1.5dB. At 0.5V to 2.0V RF it is + - 0.5dB. It is all I have. But I could try doing it on my scope as you suggest. What is the downside if the level is off, but balanced? It seems to work very well on both receive & transmit. Dial alignment is quite good.

I put the 830 on the air tonite on 80M & got very good reports using a $10 hand mic & a Turner+3 hand mic. Everyone was impressed that it was up & running. It does have a little drift. 73 - Bob

OK just wanted to make sure you were not using a dc meter to try to measure RF.

Using a RF probe you are measuring the RF carrier voltage by rectifying it with a diode and filtering it and then reading the resulting dc voltage with a Fluke DMM set on a dc range. Your RF probe sees the peak of the ac voltage level.

I think you are quoting Fluke accuracy specs?

There is no problem using any of the three instruments I previously mentioned.

If you read 0.31vdc on your Fluke that means you were reading 0.31 x 1.414 or 0.41 peak RF (ac) volts.

All is fine.

OK if you are just trying to get an inventory of spare active devices for your TS-820 then might want to start with those that are more likely to fail. Rather than just buying spares for all devices on a given board. Might ask on forum what are the more common failures.

Can also buy spare boards or a parts rig to harvest parts from. Easier to use NOS parts when you can find them.

Q9 relay switch would make my list. Here are couple more:

1. Q2 RF amp dual gate mosfet 3SK35 (GR) (most likely will have to sub)
2. Q7 AVR board Pass transistor 2SA496 (Y)
3. Q4 IF board meter FET 2SK19

Some 1N60 diodes (Scotts Electronics Crystal Radio Parts carries supply of NOS 1N60 and 1N270 diodes)

Power supply rectifier diodes and silicon switching diodes can be easily subbed.

Fortunately very seldom have any active device failures.

Others may have different experience?

A few folks reach for transistor and mosfet replacement but do so by guessing and hoping and not by troubleshooting and determining that the device has failed.

As I thought more on your comment:

If you read 0.31vdc on your Fluke that means you were reading 0.31 x 1.414 or 0.41 peak RF (ac) volts.

I understand that, but the 830 spec: 0.3V in the alignment is RMS, is it not? Actually, it is not specified. According to to the Fluke 82RF documentation: 0.25 to 0.5 RMS @10MHz will translate to 0.25-0.5VDC +- 1.5dB (When the signal get to 0.5V, the accuracy improves to +-0.5dB). Therefore no conversion to peak is require, if my RMS premise is correct. Or do RF VTVM's only read in Peak, & therefore it is understood by default that it is a peak spec? 73 Bob

Bob:

I dont know how that post happened. I did not intend to send.

Yes the value listed in the Service Manual is RMS. Your RF probe sees the peak so that is why you need to know and/or use the correct PIV rating for the signal diode. This is the only concern you should have when measuring any RF voltages in your rig. Your probe should caution you about the rf voltage measuring limit.

What this means is a typical single germanium diode probe is only good for approx 30rf volts so you can read up to the control grid on your Driver tube. Do not attempt to measure the RF voltage at plate of Driver Tube or at 6146 control grids as can burn out your probes diode.

Conversely the germanium diode barrier voltage is approx 250mv so cannot measure low level rf voltages like your TIF signal with it.

Disregard my last post. I thought I hit cancel but clearly did not.

Sorry about that.

Terry K9TW

Ron?Daniel

There is a TS820 FIX board listed on Ebay now. It is incorrectly listed as a VOX board. The guy is asking 35.00 shipped. You might write him to confirm that it is the FIX board. By the picture and the board number it is. He just has it listed as VOX board.

First trim my responses and know my post are too cryptic. Just have to give me an F on my report card. You would have been great on the Titanic arranging those deck chairs!

You would have to be living on Mars not to know that Ron and especially Daniel are working on TS820 FIX boards.

I am pretty confident they can find ebay and search on Kenwood TS820. Most folks refurbing hybrid rigs look there daily. I know I sure do.

When you can provide some constructive criticism of my KW hybrid technical responses and posts I will be glad to receive it. Never want to bum dope any of the fellows.

Ron/Daniel please contact me off list if you cannot find the FIX boards listed on Ebay.

Subject: [TS-520_820_530_830] Kenwood 520/520S Parts reduced

I thought I would let the hybrid group know that I am reducing my prices on the 520 & 520S parts.... You can find my ads on QTH.com http://qth.com/ under the HF section, just do a Search on KE5FTF... Thanks, Bob **********

45820. Ts-820S Final Cage Arcing

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Kenwood Group,

My rig arcs across somewhere near the wafers switches in the final cage. A little history...

I have some electronic technician experience, and have enjoyed restoring my inherited TS-820S. She has new finals, a new driver, a new brass band-shaft coupler.

Recently, when trying to tune-up for 10 meters using the MFJ dummy load on my antenna match, I heard a sound something like those snake type firecrackers make when burning - similar to the noise on 10 meters when the band is poor and the speaker volume is up.

I localized the arcing to an area around the wafer switch S4. I then purchased (thanks to K4EAA)and installed a new L1 rf choke, new C7 plate coupling capacitor, a new C8 plate choke bypas cap, and while I was at it new R2\3 10 ohm, and R5\6 100 ohm resistors.

The old resistors measured out-of-circuit: 10.7 and 10.7 ohms, and 104.2 and 111.2 ohms. A ball-park L1 measurement shows about 4 uH (should be 6.8 uH).

When I tested the new configuration I discovered I could tune fine, as before, to the lower bands - arcing returned at 7 MHz. I cleaned the contacts with the cheap Radio Shack spray and discovered I could tune to 7 MHz, but the arcing returned at 14 MHz.

At that point I decided I should consult the experts (you) before causing any more damage.

Thanks Terry, I think Ill give the transistor swap a try first, I did see the board on ebay and it was tempting, but I managed to find a HP1740a 100mhz scope for 108$ and I think im going to wait to install the transistors till after I get the scope so I can really trouble shoot the problem. It really helping me learn. So thanks again for all your help you've great.

Daniel

Subject: [TS-520_820_530_830] TS820 FIX Board

Ron?Daniel

There is a TS820 FIX board listed on Ebay now. It is incorrectly listed as a VOX board. The guy is asking 35.00 shipped. You might write him to confirm that it is the FIX board. By

the picture and the board number it is. He just has it listed as VOX board.

45822. ALC high in sideband positions, no RF output

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-09 22:33:55 UTC
From: <tomdulisch@...>
Topic: 45822 Message: 45822

Greetings.
New to the group and I need help with a TS-580S that until recently has been performing flawlessly.
Rig operates fine in CW position. Runs 110 watts out
into a dummy load, and indicates RF output on the rigs meter
and external wattmeter. Load and dip is normal.

In USB or LSB mode, there is zero output indicated on both
the rig meter RF position and external wattmeter. The
rigs meter goes to full deflection in the ALC position when
either the mic is keyed or even without a mic when the
send/rec switch is set to the send position.
Bias current is set at 60 ma, plate voltage slightly over
800vdc.
I have cleaned switch and contacts on the relay, replaced the driver tube.
There are no visibly burned components.

There is no connection to the remote connector or outboard
VFO. SG switch is in the on position.

Currently my only test equipment is a digital VOM.
Any clues would be appreciated.

OK learning to use a scope will be a big asset to you for troubleshooting these rigs. 100 mhz BW is good and you will now be able to look at low rf level signals like the Carrier in and out of xtal filters and the TIF signal. Hopefully it came with probes.

Have fun

Topic: 45820 Message: 45825

Not trying to be picky but you are citing component designators and values from the KW TS830 schematic from Kens website. Not the same as your TS820 components, but I get the idea.

As to L1 being 4uhy vs 6.8uhy you are OK with that value. Your schematic should call it out as a 3 uhy choke. The inductance is not too critical. The series resonance is more important for it to function as a vhf parasitic choke. My guess is there is nothing wrong with it however since it has many hours on it then I would replace it while installing one of Kens kits.

L1 serves two funcitons:
1 VHF parasitic choke
2. It provides additional series inductance for the main choke to provide enough reactance to facilitate 160 meter operation. Very hard to design a solenoid wound choke that can present enough XL across the band ratio that the Hybrids present. If you wound that additional inductance on the main choke likely would move a series resonant hole into the range and burn up the choke. One way to add the needed inductance and not move series resonant hole would be to space wind the choke on the big choke form, but then the choke would be too tall for the PA cage height limitations. So KW used the trick that 160 meter linear amp builders use and that is to insert another smaller choke is series with the big choke and place it at base of big choke and orient it at a right angle to reduce the "mutual coupling". That is called "orthogonally" and this is thrown in for free!

If interested see old ARRL Handbook for inductors and mutual coupling. More of that W5RKL fundamental stuff.

As to your PA cage arcing. First of all BE VERY CAREFUL trying to identify the location of this arcing inside the PA cage as you will be working in very close proximity to 900 vdc. Dont want to make any hand contact or drop tools or flashlite into the cage.

Couple of things come to mind
1. Fixed padder cap breaking down (in stack under plate load cap)
2. Bad L4 470uhy "safety inductor" in shunt with Plate Loading capacitor. You will see it depicted close to RL-1 TR relay on your schematic. It would be rare for it to fail. A visual may reveal signs of overheating?

L4 serves two purposes:
1. It is there to blow the transformer primary fuse if C1 Plate blocking/coupling capacitor should fail. You dont want 900vdc applied to your Pi-network, output of your SO-239 connector, your antenna coax or worse your fingers.

2. L4 also serves to prevent your tank capacitor from charging to peak of the anode voltage. It is a DC ground return. If you look at the schematic you will see that C1 .001 3KV cap is in series with the 200pf Tank cap. The tank cap is in parallel with the Load cap. So you have a capacitive voltage divider for DC voltage. Depending on how far the plates of both air variables are meshed will determine the dc voltage divider ratio. Assuming approx max capacitance then this capacitive divider of .001uf to .0018uf will

charge to the peak of 900vdc x 1.414 = 1272vdc. This ratio of capacitance will result in approx 636vdc charge across the tank and load caps. The tank cap should handle that as it is wide spaced, but the load cap cannot and perhaps the bandswitch contacts that are fed from tank coil taps cannot?

Anyway I have never see a bad safety choke in any KW hybrid. Have seen them missing. Worth checking it. If you have a LCR bridge can lift one end and measure it. Per the Service manual it is 470uhy. I have never measured one.

45826. Group rules on thread length

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-10 15:50:09 UTC
From: Mike
Topic: 45826 Message: 45826

There has been some complaints from members about the use of proper "email etiquette" where threads are not being trimmed. There is/are no group rules that require threads to be trimmed.

I will say this about long threads, they preserves the "history" of a problem which includes the symptoms, steps taken to isolate and identify the source of the problem, and the steps taken to fix the problem including components identified and replaced. It also identifies steps that should not be taken and/or components that are not part of the problem. A long thread is also a learning tool for those members who are learning to troubleshoot problems or are experiencing similar problems with/in their KW hybrids.

The bottom line is, whether a member trims their response or not is entirely up to that member. Therefore, if you don't like or care for long threads then simply don't read them, it's that simple.

Terry,

You are not being picky - just accurate. And that is exactly why your posts are so valuable.

Thank-you for the caution about high voltage. I always unplug the unit and discharge through some hefty resistors the anodes of the finals, and am careful around any components that may be holding a charge.

I read with interest the explanations of why L1 is separate, and the purpose of L4. Both descriptions help to appreciate the engineering that went into the Kenwood products, and provide insight to newbies like me on how things work.

I inspected L4 - no signs of overheating or arcing. I would like to test to see if the padding cap is breaking down. The cap is tucked under the variable loading cap - and not very accessable.

Question: Would I damage the unit by disconnecting the fixed padding cap for testing?

Topic: 45820 Message: 45828

Steve:

Well if you disconnect padder caps (from either the Plate or Load cap) then you wont be able to tune to resonance on the related bands. I think you can get a better view of this arcing if it is happening below the Load cap if you remove the fan and look thru that opening.

Does the arcing occur as you adjust either the Plate or the Load capacitor or both capacitors? Does it do it at same place in the rotation?

It is normally easier to damage the Load capacitor due to its close plate spacing.

Sometimes once the Load capacitor (3 gang close spaced one) has arced over from movable plate to fixed plate it will keep arcing over with RF as it has raised metal at the location where the arc occurred and each time you rotate plates past that same place the plate spacing is now much closer and it is now easier to arc over at that spot.

Another thing you can do is go to Jim Showkers website at HybridRestore and read his test procedure for measuring the final cage capacitors at each band switch setting. If a padder cap is breaking down I would think the capacitance value would have to be affected.

It sounds like you confirmed that the safety choke is there and not discolored so not likely the problem.

From: <wagstw46@...>
Topic: 45822 Message: 45829

Tom I did not see any responses?

Does it do this with the Mic gain turned all the way down and is the VOX off?

When you say full scale do you mean full scale deflection ie on the peg or full scale within the black printed ALC range on the meter face?

Did you try placing the meter in RF or IP and with a mic connected and mic gain turned up to say 1100 if you speak into the mic you will get RF output? Have to have audio input to the Balanced Modulator for RF output.

If this works you can adjust the mic gain to give you no more than about 1/4 to 1/3 of your 110 watts output on voice peaks (approx 25 to 30 watts) and use the rig until you can trouble shoot and fix the ALC indication issue.

Sorry, dyslexia ya know. The rig is a TS-820 S

---In TS-520_820_530_830@yahoogroups.com, <tomdulisch@...> wrote:

Greetings. New to the group and I need help with a TS-580S that until recently has been performing flawlessly.
Rig operates fine in CW position. Runs 110 watts out
into a dummy load, and indicates RF output on the rigs meter
and external wattmeter. Load and dip is normal.

In USB or LSB mode, there is zero output indicated on both
the rig meter RF position and external wattmeter. The
rigs meter goes to full deflection in the ALC position when
either the mic is keyed or even without a mic when the
send/rec switch is set to the send position.
Bias current is set at 60 ma, plate voltage slightly over
800vdc.
I have cleaned switch and contacts on the relay, replaced the driver tube.
There are no visibly burned components.

There is no connection to the remote connector or outboard
VFO. SG switch is in the on position.

Currently my only test equipment is a digital VOM.
Any clues would be appreciated.

Topic: 45820 Message: 45830

Steve:

This is probably intuitive but if you remove the fan you will need to set up a mirror to observe for arcing in the space below the Load cap as you load the rig.

Better would be to get someone who is experienced loading the rig to "drive" while you observe from behind. Might even leave the PA cage top cover on or place stiff cardboard over it so you are looking in to a darkened space.

Again be very careful.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Steve:

Well if you disconnect padder caps (from either the Plate or Load cap) then you wont be able to tune to resonance on the related bands. I think you can get a better view of this arcing if it is happening below the Load cap if you remove the fan and look thru that opening.

Does the arcing occur as you adjust either the Plate or the Load capacitor or both capacitors? Does it do it at same place in the rotation?

It is normally easier to damage the Load capacitor due to its close plate spacing.

Sometimes once the Load capacitor (3 gang close spaced one) has arced over from movable plate to fixed plate it will keep arcing over with RF as it has raised metal at the location where the arc occurred and each time you rotate plates past that same place the plate spacing is now much closer and it is now easier to arc over at that spot.

Another thing you can do is go to Jim Showkers website at HybridRestore and read his test procedure for measuring the final cage capacitors at each band switch setting. If a padder cap is breaking down I would think the capacitance value would have to be affected.

It sounds like you confirmed that the safety choke is there and not discolored so not likely the problem.

Terry,

You are not being picky - just accurate. And that is exactly why your posts are so valuable.

Thank-you for the caution about high voltage. I always unplug the unit and discharge through some hefty resistors the anodes of the finals, and am careful around any components that may be holding a charge.

I read with interest the explanations of why L1 is separate, and the purpose of L4. Both descriptions help to appreciate the engineering that went into the Kenwood products, and provide insight to newbies like me on how things work.

I inspected L4 - no signs of overheating or arcing. I would like to test to see if the padding cap is breaking down. The cap is tucked under the variable loading cap - and not very accessable.

Question: Would I damage the unit by disconnecting the fixed padding cap for testing?

> L1 serves two funcitons:
> 1 VHF parasitic choke
> 2. It provides additional series inductance for the main choke to provide enough reactance to facilitate 160 meter operation. Very hard to design a solenoid wound choke that can present enough XL across the band ratio that the Hybrids present. If you wound that additional inductance on the main choke likely would move a series resonant hole into the range and burn up the choke. One way to add the needed inductance and not move series resonant hole would be to space wind the choke on the big choke form, but then the choke would be too tall for the PA cage height limitations. So KW used the trick that 160 meter linear amp builders use and that is to insert another smaller choke is series with the big choke and place it at base of big choke and orient it at a right angle to reduce the "mutual coupling". That is called "orthogonally" and this is thrown in for free!
>
>
> If interested see old ARRL Handbook for inductors and mutual coupling. More of that W5RKL fundamental stuff.
>
>
> As to your PA cage arcing. First of all BE VERY CAREFUL trying to identify the location of this arcing inside the PA cage as you will be working in very close proximity to 900 vdc. Dont want to make any hand contact or drop tools or flashlite into the cage.

>

> Couple of things come to mind
> 1. Fixed padder cap breaking down (in stack under plate load cap)
> 2. Bad L4 470uhy "safety inductor" in shunt with Plate Loading capacitor. You will see it depicted close to RL-1 TR relay on your schematic. It would be rare for it to fail. A visual may reveal signs of overheating?
>
>
> L4 serves two purposes:
> 1. It is there to blow the transformer primary fuse if C1 Plate blocking/coupling capacitor should fail. You dont want 900vdc applied to your Pi-network, output of your SO-239 connector, your antenna coax or worse your fingers.
>
>
> 2. L4 also serves to prevent your tank capacitor from charging to peak of the anode voltage. It is a DC ground return. If you look at the schematic you will see that C1 .001 3KV cap is in series with the 200pf Tank cap. The tank cap is in parallel with the Load cap. So you have a capacitive voltage divider for DC voltage. Depending on how far the plates of both air variables are meshed will determine the dc voltage divider ratio. Assuming approx max capacitance then this capacitive divider of .001uf to .0018uf will charge to the peak of 900vdc x 1.414 = 1272vdc. This ratio of capacitance will result in approx 636vdc charge across the tank and load caps. The tank cap should handle that as it is wide spaced, but the load cap cannot and perhaps the bandswitch contacts that are fed from tank coil taps cannot?
>
>
> Anyway I have never see a bad safety choke in any KW hybrid. Have seen them missing. Worth checking it. If you have a LCR bridge can lift one end and measure it. Per the Service manual it is 470uhy. I have never measured one.

Topic: 45832 Message: 45832

Hi, my name is Pete, location Greece and I am relatively new to hybrids and to this forum.
Was wondering if there are any designs or ideas out there, about building a tuner suitable for a TS-830s?
Are there any guidelines about this?
In case this subject has been already covered, I apologize. This new Yahoo Groups look is anything but user friendly..
Is there a 'search forum' option somewhere?

Regards

Peter

But what you end up with is an exponentially-growing message, with random bits top-posted in, and it ends up being hard to read and not really making sense.

On mailing lists, we trim excess text from replies. It's just the way it's done. You know the big long thread about the correct way to tune your transmitter? You know how it's drummed into you that you don't tune up initially into the aerial, you tune up into a dummy load? Same thing. It's just the way we do it on the Internet.

If you build a Carolina Windom it will load up just fine on 40, 20, 15 and 10m without an additional tuner. Bear in mind that the pi network on the output of a valve PA is basically an ATU that expects to match a very high impedance (some thousands of ohms) to a very low (tens to hundreds).

If you're only interested in one or two bands then just make wire dipoles. At the moment my Windom is down and I've just got a dipole up for 40m - which of course loads up not too badly on 15m.

> Is there a 'search forum' option somewhere?

There was, but Yahoo! broke it.

Terry,
Thanks for the reply. I meant that the meter pegged all the way to the right on the ALC setting. There was no difference regardless of where the mic setting was, and yes the VOX was off. I did not get any indicated output in the RF setting. I think I may have solved the problem (hopefully).I I pulled all of the plugs that interconnect the boards and cleaned them, then worked them on and off a few times. The rig is currently behaving itself, I am running the mic gain at #1 position and getting 20 watts output on the peaks. I am thinking that this was 30 some odd years of oxidation on the interconnections. Thanks!

Date: 2013-11-10 22:57:01 UTC
From: clifford wright
Topic: 45832 Message: 45837

Hi Peter. Well I use my TS820S on all bands from 3.5 to 24 MHz .
My antenna is a G5RV (102 ft top with 38 ft of open wire feeders) to the shack.
My favourite antenna tuner is definitely the Z match. You can find several versions on line.
But after a lot of testing I finally went for a single coil version.
This gives over 90% efficiency
and the only band it can be a bit difficult on is 10.1 MHz where a small 1.5uH coil in series with one of the feeders cures any problems. With that I can get a virtual 1:1 SWR on all bands and my rig always sees a nice 50 Ohm load.
Windoms I have tried but you can get a lot of RF in the shack on some bands and the SWR is rarely (if ever) that close to unity.
Even dipoles have the old problem of an unbalanced feeder (coax) feeding a balanced antenna, so you still might need a balun.
The Z match is inherently a unbalanced to balanced network and open wire feeder is cheap and easy to make yourself.

Terry,

I was able to observe the general area of the arcing. It is on one of the wafer switches near the bottom of the cage and near the side of the cage near the HVT. I also noticed some carbon on the front of the wafer switch near the main choke.

I plan on taking lots of pictures and disassembling to allow for closer inspection and cleaning (replacement?) of some or all of the S4 contacts. Will probably replace all caps while there.

I am only able to work on the unit near the end of the week so it will be awhile until I have any results to report.

Thanks for the valued input! Include me as another group member who has benefited from your experiences!

> > 2. L4 also serves to prevent your tank capacitor from charging to peak of the anode voltage. It is a DC ground return. If you look at the schematic you will see that C1 .001 3KV cap is in series with the 200pf Tank cap. The tank cap is in parallel with the Load cap. So you have a capacitive voltage divider for DC voltage. Depending on how far the plates of both air variables are meshed will determine the dc voltage divider ratio. Assuming approx max capacitance then this capacitive divider of .001uf to .0018uf will charge to the peak of 900vdc x 1.414 = 1272vdc. This ratio of capacitance will result in approx 636vdc charge across the tank and load caps. The tank cap should handle that as it is wide spaced, but the load cap cannot and perhaps the bandswitch contacts that are fed from tank coil taps cannot?

Hello Peter,

I have been using a 55' (16.75 meter) long doublet fed with 600 ohm ladder line. It worked fine with the simple Kenwood AT-230 antenna tuner on most bands from 40 - 10 meters. However, the doublet antenna works much better with a tuner I built as described in a February, 1990 article in QST by Richard Measures called "A Balanced Balanced Antenna Tuner." If you are a member of the ARRL, you can download the article from their QST archives. I you are not a member of the ARRL, I will be happy to mail a PDF version of the article to you.

VY 73,

Craig

I am in the way of needing some form of antenna which might be so well hidden that a VERY restrictive Lawn Gestapo and Yard Appearance SS Waffen (Also known as a "Home Owner's Association) cannot complain of its existence.

The Ham in question is in the Carolinas, the house is currently under construction, and they're going to be moving in January or February.

The problem is that the roof contractor has placed some foam insulation boards on the underside of the actual sheathing of the roof. (Betweeb the trusses and the deck boards to which the shingles will be nailed.) That would present no real problem except that the foam boards are laminated with a fairly thick layer of aluminum foil.

The attic where we were going to install an antenna has been effectively turned into a Faraday Cage. Not a perfect one, as the individual bat of foam/foil composite are not bonded together and the entire thing grounded. But initial checks in completed portions of the attic by a local ham with a field strength meter show a marked decrease in RF compared to the uncompleted portions of the attic still open to the sky. About 80 percent signal loss, is what he told me.

Short of removing the shingles, decking, and ripping the foil off of the foam boards already placed (the roof was over three-fourths finished as of Friday evening last), is there something which can be recommended for her antenna installation?

Money is not a big deal, within reason here. (The re-roofing would be cost-prohibitive; some sort of commercial antenna with a decent tuner would NOT be out of the question.)

The antenna will be used mostly in the 40, 20, and 10 meter bands. The only real criterion is that it NOT be visible when the HOA anal-retentive idiots come knocking on their final inspection tour. (Oh, and these busy-biddies poke their noses around the neighbourhood at LEAST every week or two, so there will not be any taking it down/putting it up way around them. Also ANY other resident may (and very well might) report the violation of the HOA agreement. It HAS to be

invisible from the street.

Suggestions? Comments? Please, someone has GOT to have had this problem before. The web pages for this set of search terms are legion, but none have anything to say about this foil-lined roof problem. I will BUILD something for her and ship it from Illinois if it will get her an antenna that won't cause the HOA nosy-parkers to twitch their snouts at their house.

Thanks in advance.

Who is wondering why ANYONE would ever want to live somewhere that SNOOPS can dictate what you can and cannot have in or on your own home. I'd tend to meet those sorts at the property line, with heavy boots on, so as to be able to kick 'em a long, long way OFF of my land. www

Big aluminium flagpole mounted on insulators and a bunch of radials or chickenwire?

Just put a wire dipole up anyway, on the basis that it cannot possibly be legal to put restrictions like that on what you can and cannot do with your property? In the UK they'd get told where to go in short order.

LOLOL

So sorry to be the one to disillusion you. It most assuredly CAN be.

The "Home Owner's Associations" have a long track record of this kind of idiocy. They can tell you which colours you can or cannot paint your house or fence. They have veto power over the choice of the type of the bloody SHRUBBERY if they can make any sort of specious claim that it "lowers the property values of the other dwellings in the area."

> In the UK they'd get told where to go in short order.

Sorry, here in the Land of the FEE, they;ll sue the SOKS off you, in short order. AND you can be forced to either sell ouf even at a loss, or comply. LEGALLY.

Why do you think I used the terms "Lawn GESTAPO" and "Yard Appearance SS WAFFEN"?? I automatically "Godwinated" the post, on purpose. They really ARE that vicious, that petty, and that picky about ANYTHING and everything which can be seen in, on, or around the houses they have under their thumbs.

The original purpose of these "HOA's" was to reign in the rabid footballers and other stinking blokes who never trim the weeds they have instead of a lawn, who let the fences fall down like a set of bad teeth, and which pile garbage all about the place and put old tyre-less autos up on blocks in their side yards.

Against that sort of thing, they make some sense. Those kind of lazy bums need to be shaken up a little.

But the HOA quickly metamorphosed into petty little oligarchies, with small-minded people who, having no control over their own lives revel in dictating the details of other peoples'. It's a control and power thing, and these sorry sacks of snot enjoy every second of dragging 'miscreants' with the wrong type of sapling growing in their gardens before a judge and forcing them to cut it down.

Putting up a dipole "ANYWAY" will -not- be an option.

Now, anyone have a reasonable and useful antenna which can be kept out of sight and will provide some connection to the rest of us, despite the aluminized roof? Perhaps something along-side the gutters, which can

still get out of the back yard?

OK make sure you buy and use Class 1 caps for RF service. Also might want to contact Bob Mansker about a replacement switch as not easy to remove carbon tracking.

Dave VK5PDL has a lot of experience replacing these padder caps and may have a source of replacement capacitors.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <kk6ezq@...> wrote:

Terry,

I was able to observe the general area of the arcing. It is on one of the wafer switches near the bottom of the cage and near the side of the cage near the HVT. I also noticed some carbon on the front of the wafer switch near the main choke.

I plan on taking lots of pictures and disassembling to allow for closer inspection and cleaning (replacement?) of some or all of the S4 contacts. Will probably replace all caps while there.

I am only able to work on the unit near the end of the week so it will be awhile until I have any results to report.

Thanks for the valued input! Include me as another group member who has benefited from your experiences!

The series resonance is more important for it to function as a vhf parasitic choke. My guess is there is nothing wrong with it however since it has many hours on it then I would replace it while installing one of Kens kits.
> >
> >
> > L1 serves two funcitons:
> > 1 VHF parasitic choke
> > 2. It provides additional series inductance for the main choke to provide enough reactance to facilitate 160 meter operation. Very hard to design a solenoid wound choke that can present enough XL across the band ratio that the Hybrids present. If you wound that additional inductance on the main choke likely would move a series resonant hole into the range and burn up the choke. One way to add the needed inductance and not move series resonant hole would be to space wind the choke on the big choke form, but then the choke would be too tall for the PA cage height limitations. So KW used the trick that 160 meter linear amp builders use and that is to insert another smaller choke is series with the big choke and place it at base of big choke and orient it at a right angle to reduce the "mutual coupling". That is called "orthogonally" and this is thrown in for free!

I was serious about the flagpole. Surely they can't object to that?

Get a 5m pole, mount it on some sort of insulated plinth and stick a tapped coil inside to match it for 80, 40 and 20. Performance won't exactly be stellar on 80 but it'll be quite acceptable on 40 and 20, and not look too ridiculous.

I did pretty much this with a "silver rod" type CB aerial back when I got licensed first - not so much due to neighbour issues as because I had a tiny suburban back garden just about big enough for a dipole for 10 spaced reasonably far from the house. With 10W (legal limit for MM3 licenses, achievable with the ALC biasing trick) I wasn't going to win any prizes but I got my logbook nice and full...

So, stick up a 5m flagpole, and if no-one starts shouting load it up and see what happens :-)

I enjoy reading all the threads, even the long ones. I got my degree in 1970 and a lot of stuff has made great changes sense then. Being 68 yrs. now it is sometime hard to remember a lot of the things I have learned. I have serviced all kinds of electronics over the years, but not as a job, but more like a hobby. Reading through some of these threads is almost like going back to school as some of the stuff I had forgotten. Terry has refreshed my marbles a few times and I am very thankful for it. I know it takes time to read all of these, but in the long run it is good to refresh the gray matter and for the nubee's, its an education time. I thank all of you for the help. Thanks to all the Veteran's out there that have served to keep our country free and so we can read threads like this. God Bless All.

Bill WD8OSJ

---In TS-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

There has been some complaints from members about the use of proper "email etiquette" where threads are not being trimmed. There is/are no group rules that require threads to be trimmed.

I will say this about long threads, they preserves the "history" of a problem which includes the symptoms, steps taken to isolate and identify the source of the problem, and the steps taken to fix the problem including components identified and replaced. It also identifies steps that should not be taken and/or components that are not part of the problem. A long thread is also a learning tool for those members who are learning to troubleshoot problems or are experiencing similar problems with/in their KW hybrids.

The bottom line is, whether a member trims their response or not is entirely up to that member. Therefore, if you don't like or care for long threads then simply don't read them, it's that simple.

Having had a similar issue with the Waffen SS lawn gestapo in California, I used a loop of wire run around the eaves of the roof and fed with RG58 thru a balun. While assuredly NOT the world's greatest, I did get out and have a somewhat usable signal. I used 12ga THHN with brown insulation to match the roof.

The lawn gestapo once "fined" us because the grass was 7/8" long, exceeding the dictated 3/4". When I refused to pay, they took us to court - I prevaled when I asked the Court to order the minifuhrer to provide the NIST-traceable calibration certificate for his ruler and the approved procedure for lawn height measurement. Yes, they truly ARE that bad. Never again!

Subject: Re: [TS-520_820_530_830] TS-830S DIY Antenna Tuner

Having had a similar issue with the Waffen SS lawn gestapo in California, I used a loop of wire run around the eaves of the roof and fed with RG58 thru a balun. While assuredly NOT the world's greatest, I did get out and have a somewhat usable signal. I used 12ga THHN with brown insulation to match the roof. The lawn gestapo once "fined" us because the grass was 7/8" long, exceeding the dictated 3/4". When I refused to pay, they took us to court - I prevaled when I asked the Court to order the minifuhrer to provide the NIST-traceable calibration certificate for his ruler and the approved procedure for lawn height measurement. Yes, they truly ARE that bad. Never again!JohnKD5ZGX On Monday, November 11, 2013 5:44 AM, Gordon JC Pearce <gordon@...> wrote:

I was serious about the flagpole. Surely they can't object to that?

Get a 5m pole, mount it on some sort of insulated plinth and stick a tapped coil inside to match it for 80, 40 and 20. Performance won't exactly be stellar on 80 but it'll be quite acceptable on 40 and 20, and not look too ridiculous.

I did pretty much this with a "silver rod" type CB aerial back when I got licensed first - not so much due to neighbour issues as because I had a tiny suburban back garden just about big enough for a dipole for 10 spaced reasonably far from the house. With 10W (legal limit for MM3 licenses, achievable with the ALC biasing trick) I wasn't going to win any prizes but I got my logbook nice and full...

So, stick up a 5m flagpole, and if no-one starts shouting load it up and see what happens :-)

Hello Peter,

I have been using a 55' (16.75 meter) long doublet fed with 600 ohm ladder line. It worked fine with the simple Kenwood AT-230 antenna tuner on most bands from 40 - 10 meters. However, the doublet antenna works much better with a tuner I built as described in a February, 1990 article in QST by Richard Measures called "A Balanced Balanced Antenna Tuner." If you are a member of the ARRL, you can download the article from their QST archives. I you are not a member of the ARRL, I will be happy to mail a PDF version of the article to you.

Well the other Ham in my street has a multi band beam. But he also has a very unobtrusive vertical.
My own aluminium masts are both insulated and used as verticals on 10.1 and 14 MHz with results only about 5 dB down on the G5RV. I don't think flying the flag can be complained of too much even by the most restrictive local authorities in the USA in particular.
They have a base matching network which can be controlled from the station with a simple relay circuit and give a very good match to 50 Ohms on those bands.
BTW I've been thinking about it myself for when we move to a pensioner housing area.
Years ago I had an attic antenna while we were flatting, but it was a great picker up of local interference even though it was under a clay tile roof, so I would not recommend it as a solution anyway. The vertical is probably the best way to go. Though how about an "invisible" dipole? if thin wire is used and small glass insulators it can be quite hard to see.

Just a thought. Am I right in saying you have a right to fly a flag and if so a vertical antenna could be hidden in such a pole!

With sincere apologies, I must retract my offer of providing a PDF copy of the February, 1990 QST article "A Balanced Balanced Antenna Tuner." Ownership of the article is the ARRL's, and I do not wish to violate the copyright law. As I said originally, the article is available for download to ARRL members -- along with nearly any other article ever published in QST and QEX. Access to this vast library, is, in my opinion, worth the price of membership alone.

The piece in question by Richard Measures is, however, available online elsewhere and can be located easily through search engines. Again, my apologies.

Oh -- Happy Veterans Day! I invite all to join my fellow vets on 14.275 MHz from 1300 - 2200 UTC today for The American Legion Amateur Radio Club's "Salute to Veterans". My colleagues in Indianapolis will be operating special event station W9L.

Details are at
http://www.legion.org/hamradio/clubupdates/217757/legion-salute-veterans-over-airwaves

I am now off to Arlington National Cemetery and the Vietnam Veterans Memorial ("The Wall") to cover the events of this special day.

I have wintered in Florida since the late 80s and lived in condos on the beach, adult parks, and residential neighborhoods and in every case the HOA has not allowed any kind of outdoor antennas Ham, TV, FM, and in some cases no satellite dishes. Only cable was allowed..

Partly in their defense you know these rules going in. If you allowed outdoor TV antennas you would have every config under the sun and mounted in manners you could not even imagine. Everyones definition of professional installation varies greatly. Same for working on your car in the drive way it is not allowed. Not even changing oil. No cars up on blocks or jacks etc. It sounds gestapo like, but drive thru any of the myriad of adult trailer parks that abound in Florida that have no such restrictions and you will see the difference. Some real eyes sores.

Where I currently live I tried to sneak a wire under the eaves of my park model trailer and a nosy neighbor (we have self appointed sheriffs!) reported me. The small gauge wire came down.

So I spent the money as so many Snow Bird hams do and bought a ve rtical and placed it inside a fiberglass flag pole. Not cheap. Since lot size is small and no way to install a decent radial system in the off season I went down and buried a ground lead out to the pond that I am on and connected it to a metal plate and submerged it. As long at the pond level stays up I should be OK.

Now that I have published my transgressions someone will surely turn me in and my operation will then be limited to Virtual Ham Radio operation like Hamsphere.

What is wrong with these?

I see no mast supported by cinder blocks, no off plumb 4x4 post sunk in the yard, no lag bolts securing 2x4 lumber to side of house, no mast held up with bungee cords lashed to deck post, no mast bent or leaning at 45 degrees, no feed line strung at head height.

Terry

In America the answer is "Yes" you can fly the flag on a Flag Pole.

Many hams use "Flag Pole Antennas", I worked a station yesterday on 40 meter CW that was using a "Flag Pole Antenna".

The following link is a company that sells Flag Pole antennas.

http://www.theflagpoleco.com/tefl.html

However, before any ham who lives in an HOA restricted development decides to put up a Flag Pole antenna, they should read their HOA agreement thoroughly. The agreement could specify the "type" of flag pole that's acceptable and it could be something as simple as a Flag Pole that is mounted on a porch support post ONLY, not a Flag Pole in the middle of the front yard. So read your HOA restrictions FIRST before you purchase a Flag Pole antenna!

One of my ham buddies and work colleagues had lived with the compromises of an attic antenna for years due to neighborhood association restrictions. But, he recently erected a commercial flagpole antenna with excellent results. The association would not allow him to put the flagpole in his front yard, however, due to "political sensitivities." Undaunted, he put it up in his back yard, American flag proudly fluttering at the top (and radials neatly hidden 'neath the lawn).

There's (almost) always a way.

Federal law (I think, may be it is a state law here in Nevada) prevents HOA's from restricting satellite dishes.

Yeah..ya gotsta read da rules that some HOA's put out, about flags. In one hoity-toity section of Reno, one is only allowed to fly the flag during recognized National holidays, and even at that, it can only fly from a pole assembly, attached to the frame of the front door, and must hang at a specified angle (Which I don't know). One gentleman is a M.o.H , recipient and put up a flagpole and flag, in his front yard. His HOA threatened to take it down and then 'fine' him. When they went to court to force him to take it down, the courts ruled he had every right to fly the flag, in any manner he so chose....The court did say that the ruling only applied to this gentleman, and that any antenna actions in the future would have to be decided on their own merits.

IMMHO, HOA's can stick their rules up their backsides, when dealing with Vets. They earned the right to fly the flag in any way they so choose!

Thanks you to all the Veterans out there!

In America the answer is "Yes" you can fly the flag on a Flag Pole.

Many hams use "Flag Pole Antennas", I worked a station yesterday on 40 meter CW that was using a "Flag Pole Antenna".

The following link is a company that sells Flag Pole antennas.

http://www.theflagpoleco.com/tefl.html

However, before any ham who lives in an HOA restricted development decides to put up a Flag Pole antenna, they should read their HOA agreement thoroughly.

Ya know..if anyone tried to restrict me from flying the flag, due to 'political sensitivities', I would have told them to put it where the sun don't shine. I am an American, and I will proudly fly the American Flag, when ever and where ever I choose..there should be only one political motive in flying the American Flag, **PATRIOTISM**!! Any that find that 'insensitive', can leave this country.

To our neighbors from Canada, or Overseas, I would expect the same reactions to someone stating a 'political sensitivity' as a reason to not fly *YOUR* flag.

(This is a soapbox I will never stand down from!)

>
> Partly in their defense you know these rules going in. If you allowed outdoor TV antennas you would have every config under the sun and mounted in manners you could not even imagine. Everyones definition of professional installation varies greatly. Same for working on your car in the drive way it is not allowed. Not even changing oil. No cars up on blocks or jacks etc. It sounds gestapo like, but drive thru any of the myriad of adult trailer parks that abound in Florida that have no such restrictions and you will see the difference. Some real eyes sores.

45863. Whackamole update

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-11 20:32:57 UTC
From: <rrmvargo@...>
Topic: 45863 Message: 45863

I know you guys/gals are getting sick of this, but I have a new update that some may find useful.

My TS-830S that was given to me is now working quite well. I made an adapter for my MD100 mic & I get very good audio reports running the compression at 9:00 & mic gain just past 12:00.

But one thing that I did not like was the VFO drift. If I was to leave the radio on for 2 hours, it would drift upward in frequency 200-400Hz or more. I would regularly touch up the VFO knob to get back to where I started.

I searched here & the internet to find solutions to the drift but was never completely satisfied with what I found. So I removed the VFO for a look.

Not much there. Some brass gears, variable cap, 4 transistors, caps & resistors. So I added 2 drops of DeOxit to each end of the variable where the wipers are & I removed the 2 screws at the back end of the board where it grounds out to the chassis. I slipped 2 star washers under the board & reinstalled the screws. I cleaned the pins on the VFO connector that comes from the radio & reinstalled everything.

Now I didn't expect much, but it made an incredible improvement on my 830. Stability now stays within 100Hz over a few hours. Since the digital res is only good for 100Hz, it is hard to tell just how good it is.

So if you have some drift, & nothing else worked, you might try this.

73 - Bob

Keep it up, OM, and people are going to start asking you to fix their
rigs for them....

Good for you, glad to hear that it is back up to snuff. Gives me hope
that I'll be able to do the same when my rig gives me the gyp eventually.

I think if I ever have to pull anything which requires a chassis ground
through a mounting screw like that, from now on I'm not just going to
polish the spot and the stand-off, but I'll put a star washer on there
too, every time.

Steve,

If you do as Terry has suggested and are going to use a long metal mirror, please insult the entire length as there is very little room and lots of potential. If your removing the fan and going in from the rear, make sure you insulate the 100v wires to the fan, have been bitten once or twice. If you do have issues with the padder caps, let me know and I can pull up my invoices and let you know where to get them from. Also if you let me know the values your looking for, Class 1 type caps in VK are now a special order.

Subject: [TS-520_820_530_830] RE: RE: Re: Ts-820S Final Cage Arcing

Steve:

This is probably intuitive but if you remove the fan you will need to set up a mirror to observe for arcing in the space below the Load cap as you load the rig.

Better would be to get someone who is experienced loading the rig to "drive" while you observe from behind. Might even leave the PA cage top cover on or place stiff cardboard over it so you are looking in to a darkened space.

Again be very careful.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Steve:

Well if you disconnect padder caps (from either the Plate or Load cap) then you wont be able to tune to resonance on the related bands. I think you can get a better view of this arcing if it is happening below the Load cap if you remove the fan and look thru that opening.

Does the arcing occur as you adjust either the Plate or the Load capacitor or both capacitors? Does it do it at same place in the rotation?

It is normally easier to damage the Load capacitor due to its close plate spacing.

Sometimes once the Load capacitor (3 gang close spaced one) has arced over from movable plate to fixed plate it will keep arcing over with RF as it has raised metal at the

location where the arc occurred and each time you rotate plates past that same place the plate spacing is now much closer and it is now easier to arc over at that spot.

Another thing you can do is go to Jim Showkers website at HybridRestore and read his test procedure for measuring the final cage capacitors at each band switch setting. If a padder cap is breaking down I would think the capacitance value would have to be affected.

It sounds like you confirmed that the safety choke is there and not discolored so not likely the problem.

Terry K9TW

Terry,

You are not being picky - just accurate. And that is exactly why your posts are so valuable.

Thank-you for the caution about high voltage. I always unplug the unit and discharge through some hefty resistors the anodes of the finals, and am careful around any components that may be holding a charge.

I read with interest the explanations of why L1 is separate, and the purpose of L4. Both descriptions help to appreciate the engineering that went into the Kenwood products, and provide insight to newbies like me on how things work.

I inspected L4 - no signs of overheating or arcing. I would like to test to see if the padding cap is breaking down. The cap is tucked under the variable loading cap - and not very accessable.

Question: Would I damage the unit by disconnecting the fixed padding cap for testing?

> Not trying to be picky but you are citing component designators and values from the KW TS830 schematic from Kens website. Not the same as your TS820 components, but I get the idea.
>
>
> As to L1 being 4uhy vs 6.8uhy you are OK with that value. Your schematic should call it out as a 3 uhy choke. The inductance is not too critical. The series resonance is more important for it to function as a vhf parasitic choke. My guess is there is nothing wrong with it however since it has many hours on it then I would replace it while installing one of Kens kits.
>
>
> L1 serves two funcitons:
> 1 VHF parasitic choke
> 2. It provides additional series inductance for the main choke to provide enough reactance to facilitate 160 meter operation. Very hard to design a solenoid wound choke that can present enough XL across the band ratio that the Hybrids present. If you wound that additional inductance on the main choke likely would move a series resonant hole into the range and burn up the choke. One way to add the needed inductance and not move series

resonant hole would be to space wind the choke on the big choke form, but then the choke would be too tall for the PA cage height limitations. So KW used the trick that 160 meter linear amp builders use and that is to insert another smaller choke is series with the big choke and place it at base of big choke and orient it at a right angle to reduce the "mutual coupling". That is called "orthogonally" and this is thrown in for free!
>
>
> If interested see old ARRL Handbook for inductors and mutual coupling. More of that W5RKL fundamental stuff.
>
>
> As to your PA cage arcing. First of all BE VERY CAREFUL trying to identify the location of this arcing inside the PA cage as you will be working in very close proximity to 900 vdc. Dont want to make any hand contact or drop tools or flashlite into the cage.
>
>
> Couple of things come to mind
> 1. Fixed padder cap breaking down (in stack under plate load cap)
> 2. Bad L4 470uhy "safety inductor" in shunt with Plate Loading capacitor. You will see it depicted close to RL-1 TR relay on your schematic. It would be rare for it to fail. A visual may reveal signs of overheating?
>
>
> L4 serves two purposes:
> 1. It is there to blow the transformer primary fuse if C1 Plate blocking/coupling capacitor should fail. You dont want 900vdc applied to your Pi-network, output of your SO-239 connector, your antenna coax or worse your fingers.
>
>
> 2. L4 also serves to prevent your tank capacitor from charging to peak of the anode voltage. It is a DC ground return. If you look at the schematic you will see that C1 .001 3KV cap is in series with the 200pf Tank cap. The tank cap is in parallel with the Load cap. So you have a capacitive voltage divider for DC voltage. Depending on how far the plates of both air variables are meshed will determine the dc voltage divider ratio. Assuming approx max capacitance then this capacitive divider of .001uf to .0018uf will charge to the peak of 900vdc x 1.414 = 1272vdc. This ratio of capacitance will result in approx 636vdc charge across the tank and load caps. The tank cap should handle that as it is wide spaced, but the load cap cannot and perhaps the bandswitch contacts that are fed from tank coil taps cannot?
>
>
> Anyway I have never see a bad safety choke in any KW hybrid. Have seen them missing. Worth checking it. If you have a LCR bridge can lift one end and measure it. Per the Service manual it is 470uhy. I have never measured one.

Willard

Remember when you key the mic there can be no transmit rf output until you speak in the mic (modulate the radio) unless you have not nulled the Balanced Mod carrier properly.

Should only see steady 60ma resting plate current when you key the mic.

What is your resting plate current (Ip) doing? I check this with rig in LSB/USB with mic gained turned down.

Terry K9TW

I have the exact same problem! Just started last week. the 820 tunes up fine, just like always. Key the mike and WHAM, pins the alc and no transmit. If I hold the key down for a bit, the alc will slowly go down and the rig will start to transmit, but the alc never goes all the way down. I'm sure my tuning process is ok, since I am experienced on tube rigs. Call was WN6TOE in 1975. Any help will be much appreciated!, Tnx! Will KJ6JKA

Terry,

Food for thought,
Just read you post on the antenna restriction. I knew a ham in the same boat as you.
What he did was install 2 sets of gutter heaters with a tuner.
One to melt the ice in the winter and the other As an antenna.

I knew another ham that remove the first metal el-bow from his gutters and
Replaced with plastic as well as the short pipe about 2 feet long. He ran a ground wire through the
Gutter to a stake next to the downspout. The front and rear gutter were about 60 feet long
And all in one piece as they were custom made. The facers are vinyl so no interaction.
He set up a co-phase system. He can run parallel or in series.
He loaded the gutters with a tuner and works all bands with ease. 10 meters is hard to tune
But it does work. Less than 2 – 1 across the bands.

Co-phase May not be the right term.

I have wintered in Florida since the late 80s and lived in condos on the beach, adult parks, and residential neighborhoods and in every case the HOA has not allowed any kind of outdoor antennas Ham, TV, FM, and in some cases no satellite dishes. Only cable was allowed..

Partly in their defense you know these rules going in. If you allowed outdoor TV antennas you would have every config under the sun and mounted in manners you could not even imagine. Everyones definition of professional installation varies greatly. Same for working on your car in the drive way it is not allowed. Not even changing oil. No cars up on blocks or jacks etc. It sounds gestapo like, but drive thru any of the myriad of adult trailer parks that abound in Florida that have no such restrictions and you will see the difference. Some real eyes sores.

Where I currently live I tried to sneak a wire under the eaves of my park model trailer and a nosy neighbor (we have self appointed sheriffs!) reported me. The small gauge wire came down.

So I spent the money as so many Snow Bird hams do and bought a ve rtical and placed it inside a fiberglass flag pole. Not cheap. Since lot size is small and no way to install a decent radial system in the off season I went down and buried a ground lead out to the pond that I am on and connected it to a metal plate and submerged it. As long at the pond level stays up I should be OK.

Now that I have published my transgressions someone will surely turn me in and my operation will then be limited to Virtual Ham Radio operation like Hamsphere.

I suspect my neighbors and HOA might question my sanity if I was to install heat tapes on my gutters at my Fort Myers Beach Florida home!

Thanks for the thought.

Maybe some of our Northern members can consider this if have HOA restrictions.

Y'know... If you had a squarish house and aluminium guttering with stratigically-placed plastic joiners, you could turn them into a Moxon at some frequency...

When I was in college at TAMU there was no way to put a beam on the roof...I struggled with a vertical then ran a dipole from one dorm to the next but the wire was so small to avoid observation that the wind was an issue. What I eventually did was build me a DDR on the top of the dorm. (flat roof)...for HF it worked pretty good..and was amazing immune to TVI. I have thought about doing that again on my apartment building here in Dhaka...I am on the 7th floor of eight...and while I am getting a beam for the upper H bands..>I want to give the lower ones a try. Was up on the roof today thinking of it. Robert WB5MZO/S2

sorry for the slow reply yes the the L1 on if is low but the FET it feeds is OK but the if cans L2 L5 L6 do not tune so it is either that they are not working or the mixer is not working as i do not have a manual i am not sure what i should read and where but i am looking for a manual so as to speed things up.
thank you

peter

A damaged L1 of the BCB filter on the RF board make sense, but accidental Transmit should never have got to L1 at RIF input to common gate RF amp on the IF board. If it did the RIF Mixer on RF board would have been damaged.

I would never remove L1 or any other component on IF board until replacing L41 and doing good Coil Pack alignment and RF and IF alignment.

DId you replace L1 on IF board? It is there for a reason.

45879. 6146B test Data?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-12 19:51:42 UTC
From: Chris Maness
Topic: 45879 Message: 45879

I have an older mutual conductance/emission tube tester. It does not list the newer 6146B's as many do not. All of my 6146B's test at 120%. The knob that adjusts the meter level for pass/fail on my B&K 700 is the sensitivity adjustment. Does anybody know what percentage of correction should be made (assuming it is linear) to bring it in line with the A version of the tubes emission reading? I understand the tubes are similar, but the cathode coating is different giving the B version higher conductance.

Thanks,
Chris Maness KQ6UP

The state of Florida has a law that allows any homeowner to erect a flagpole up to 20' in height regardless of HOA restrictions or deed restrictions. I have a Hy-Gain 18' vertical with a pulley on the top. If challenged I can always raise the flag I have in standby.

Hi Chris,

I'm not familiar with the B&K tester but if you can measure the
voltages on the pins (maybe on one of the unused sockets?) and the
plate current you can work out the gm for a tube and cross check it
to the specification sheet.

Here's some simple math to work it out

http://tubes.nekhbet.com/math.shtml

Here's the spec sheet for the 6146B

http://frank.pocnet.net/sheets/079/6/6146B.pdf

Alternatively, you could use your tubes as the baseline for future
testing and set the sensitivity to 100%.

Terry,
Food for thought,
Just read you post on the antenna restriction. I knew a ham in the same boat as you.
What he did was install 2 sets of gutter heaters with a tuner.
One to melt the ice in the winter and the other As an antenna.
 I knew another ham that remove the first metal el-bow from his gutters and
Replaced with plastic as well as the short pipe about 2 feet long. He ran a ground wire through the
Gutter to a stake next to the downspout. The front and rear gutter were about 60 feet long
And all in one piece as they were custom made. The facers are vinyl so no interaction.
He set up a co-phase system. He can run parallel or in series.
He loaded the gutters with a tuner and works all bands with ease. 10 meters is hard to tune
But it does work. Less than 2 – 1 across the bands.
Co-phase May not be the right term.

The house is 60' x 35' So if you wanted to make an 80 meter Moxon it might just be right. He has his WAS and WAC from the ARRL and completed them in one year. I don't think he has to worry much about an antenna.

Y'know... If you had a squarish house and aluminium guttering with stratigically-placed plastic joiners, you could turn them into a Moxon at some frequency...

And all in one piece as they were custom made. The facers are vinyl so no interaction.
He set up a co-phase system. He can run parallel or in series.
He loaded the gutters with a tuner and works all bands with ease. 10 meters is hard to tune
But it does work. Less than 2 – 1 across the bands.

Co-phase May not be the right term.

I have wintered in Florida since the late 80s and lived in condos on the beach, adult parks, and residential neighborhoods and in every case the HOA has not allowed any kind of outdoor antennas Ham, TV, FM, and in some cases no satellite dishes. Only cable was allowed..

Partly in their defense you know these rules going in. If you allowed outdoor TV antennas you would have every config under the sun and mounted in manners you could not even imagine. Everyones definition of professional installation varies greatly. Same for working on your car in the drive way it is not allowed. Not even changing oil. No cars up on blocks or jacks etc. It sounds gestapo like, but drive thru any of the myriad of adult trailer parks that abound in Florida that have no such restrictions and you will see the difference. Some real eyes sores.

Where I currently live I tried to sneak a wire under the eaves of my park model trailer and a nosy neighbor (we have self appointed sheriffs!) reported me. The small gauge wire came down.

So I spent the money as so many Snow Bird hams do and bought a ve rtical and placed it inside a fiberglass flag pole. Not cheap. Since lot size is small and no way to install a decent radial system in the off season I went down and buried a ground lead out to the pond that I am on and connected it to a metal plate and submerged it. As long at the pond level stays up I should be OK.

Now that I have published my transgressions someone will surely turn me in and my operation will then be limited to Virtual Ham Radio operation like Hamsphere.

All the talk about tuners reminded me - I've got a Kenwood AT-200 tuner in great shape that I am thinking about selling. At least an 8 out of 10 for looks and performance. Christmas is coming and I need to sell some stuff! $195 plus $20 shipping in the continental US. If nobody's interested it might go up on ebay sometime soon. There's one way over $200 selling right now.

I've got a Washburn Idol Pro like brand new with box and tags (played very little) that I need to sell since I just bought a new guitar, too...

Hello to all,

I have recently purchased one of these units. Unfortunately the seller did not disclose that it does not receive. My certified Kenwood repair guru confirmed this. The unit does get power, the internal speaker hisses but otherwise I cannot tell what works and what doesn't. I do not have a microphone yet (mainly because I have no license yet and wanted to figure out the workings of the radio and to listen to the world) so transmitting wasn't an issue but I'll want to try it sometime.

So, I am wondering if anyone has had to address the issue of not receiving and what steps anyone took to resolve said issue.

Now, please bear in mind that ham jargon is a foreign language to me. Plain English will be appreciated because I have no idea what any abbreviations mean.

Thanks in advance

It has nothing to do with Ham Jargon; it simply has to do with your electronic expertise. In all honesty, if you do not understand the electronics, do not open that radio. There is high voltage in the unit even if you do not wish to transmit. You can test that after the fact of a license or someone with you so they can teach you how to tune it up. So from the beginning, first thing to do is to try and pry out of the seller just what the radio was used for, Ham or CB which the latter would have been illegal and hopefully the inside has not been trashed. Second or at the same time, READ your manual, understand the whole thing. Read a service manual as well, basically the description of operation. If you know a certified Kenwood repairman, maybe he will fix it for you, but you should understand the operation including proper tuning of the finals. Since you plan to get a license, simple items you will need is an antenna. And a Dummy load for at least 100 watts and maybe a DVM or digital volt meter.

This will help you out and give you some understanding of the radio. Get a book on the tech license and read that as well. Have fun Brad KB2CHY

I would 2nd those comments. As soon as you hit that power button, there are LETHAL voltages inside the radio. Even the well experienced tech can be fooled or become unencumbered by the thought process. Now just because you are not a licensed Ham at this point, doesn't mean you aren't a very experienced tech. If so, let us know. Regardless, keep one hand inside your pocket should you decide to open up the 820. 73 - Bob

Just purchased a "working" 520S on Ebay....here we go! This radio did take one hell of a beating...arrived with the cooling fan smashed in as well as 2 corners. I worked out the difference with the seller. In the mean time, it actually does turn on, transmits, receives normal volume static out of speaker, all switches and knobs act normal, BUT the sensitivity is low on all bands. I can hear stations but they are way below what they should be.
I've done the obvious, RF Gain check, alignment, Voltages. Then I've looked for loose wires especially on the Fix Channel board and Function switch...nothing I can find. In addition: the calibrator signal is very sick...sounds like a Walrus in the distance every 25 Khz. You still do need to adjust the drive to hear it as well as other stations. Could someone point me in a direction. Is a diode or transistor the next culprit? I'm just still thinking something got knocked loose. Any help would be appreciated.

My question just before that would be "Have you got an aerial connected?"

You won't hear *anything* other than incredibly strong stations in the next room, without that.

I can hear stations but they are way below what they should be.
I've done the obvious, RF Gain check, alignment, Voltages. Then I've looked for loose wires especially on the Fix Channel board and Function switch...nothing I can find. In addition: the calibrator signal is very sick...sounds like a Walrus in the distance every 25 Khz. You still do need to adjust the drive to hear it as well as other stations. Could someone point me in a direction. Is a diode or transistor the next culprit? I'm just still thinking something got knocked loose. Any help would be appreciated.

Also did the tapping on the relay without success.

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Well Airwolff!
I regret to say that you don't really have the right equipment for your level of expertise.
The Kenwood Ts820 is quite a complex bit of kit. Of course this means that there could be dozens of possibilities for a fault. I have restored and updated 2 of them, but then I have 60 years of electronics experience behind me.
So my own feeling is that you would be better off with a more modern type of receiver for now.
Although the Kenwood hybrids are great sets to tinker with, they do need a LOT of know how especially as they combine both tube and semiconductor technology (and dangerous high voltages!!).
So, I hope you succeed in your efforts, but you will need a very good "Elmer" to help out at the very least.

How did your "certified" Kenwood repair guru confirm that the radio does not receive?

Did he have the radio in his possession or was his confirmation based on talking you thru some form of testing?

You have been given good advice not to remove the covers and to obtain the operating and service manuals and start reading for starters..

I would suggest that since you want to just listen at this time to make sure that the Send/Receive switch is placed in Receive and left there, the CAR level control is set full CCW, and that the Heater switch is left in the OFF position. This ensures that there is no way to have any unintentional transmit that could damage your final tubes.

Read the operating manual and familiarize yourself with the controls. Then pre-set all the controls for Receive mode as listed under Section 4.2 Receiver Tuning Table 1.

One test you can do that will tell you something about the Coil Pack and RF and IFT alignment is:

1. Set the VFO to approx 200 (Band switch at 14mhz)
2. Set the Drive Control to 1200
3. Set the RF Gain to Full CW or max open (AF gain to comfortable level)
4. Set the Function Switch to 25khz (Marker or Crystal calibrator on)
5. Tune the VFO around 200 until you hear the Marker signal
6. Peak the Marker signal using the Drive Control (peak = max deflection on S meter)
7. Should see approx S9 indication on the S-meter
8. Repeat this procedure on each band.

If you can peak the Marker signal on each band to approx S9 you know that the receiver RF and IF stages are functioning and alignment is pretty good. The rig should be able to copy off air signals.

Make sure you turn off Marker when done.

As someone mentioned connect as much wire as you can to the SO-239 antenna connector on rear of rig (single lead inserted into the center will work). Wont work as well as resonant dipole, but should be able to copy off air signals. Probably listen on 40 meters for starters.

If that works then suggest you put up a 40 meter dipole or inverted Vee as high as you can for starters. Will receive much better than piece of wire strung around perimeter of your room.

If you get no Maker signal or very low Marker signal, you need hands on help from a "certified" Kenwood guru. Not sure what that means, but can get the help here but will be slow and tedious to talk you thru tests and repairs. Local club may produce and Elmer?

I forgot to mention that Butch also gave you good advice to confirm that Pins 8 and 9 jumper is installed in the External VFO socket on rear panel. Your manual shows this in Figure 4 around page 8. Your guru should have confirmed this.

If the black plug is missing you can use a piece of hook-up wire but not the best and must be correct gauge to make reliable contact as it is inserted into the socket. This jumper provides 9vdc regulated supply to your internal VFO.

45907. CW/Tune TX offset adjustment TS820S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-15 14:38:37 UTC
From: <zigs68@...>
Topic: 45907 Message: 45907

Hi all -

I was trying to read through previous posts on this and there was some mention of how to adjust the CW/Tune TX offset to get the normal 800 Hz from what I read was the TX frequency for USB. The TS820S I have seems to show an offset of 400 Hz only according to the display which on receive is rather accurate judging by the signals I am receiving and that the WWV signal received is accurate to the display. Now it could be that the display is not reading this right but how do you adjust the CWTune offset if it is off?

The previous posts mentioned fiddling with trimmers on CAR1 and CAR2 but they were not too specific on the details. I see in the service manual a carrier unit adjustment which may take care of this offset perhaps? The radio works fine otherwise after fixing an intermittent no TX issue which was traced to a loose set of what I call header pins on the IF board that was re-soldered and the TX works fine now

Any info would be great - Sig - KB2HHU

Airwolff,

I'll assume that the rear remote VFO socket has either the factory 9 pin plug inserted or a wire connecting pins 8 and 9 together.

You did not mentioned whether your TS-820 has the digital display or not. If your TS-820 does, in fact, have the digital display and with your TS-820 powered up, what is the digital display showing? If it's "dark", nothing displayed, then that is a clear indication the TS-820's PLL Unit has changed states from "Lock" to "Unlock". This is a simple test you can perform without removing any covers and it is a test your "certified Kenwood guru" should have asked you!

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

Yes no PLL then no reason to check Maker signal strength.

No Display usually and most commonly means PLL is unlocked, but not always. Can be a bad display.

I would call it more of a symptom or description of the current operational condition than a "test", but an important piece of information that would be readily apparent if rig was on the bench. .

I clearly failed to ask about this so good reason why I am not a "certified" Kenwood guru!

If anyone knows how one attains that certification I would be interested in the study guides and where and who administers the test. I am not kidding.

Perhaps what we are really talking about is an "authorized dealer" or "service center?

Airwolff,

I'll assume that the rear remote VFO socket has either the factory 9 pin plug inserted or a wire connecting pins 8 and 9 together.

You did not mentioned whether your TS-820 has the digital display or not. If your TS-820 does, in fact, have the digital display and with your TS-820 powered up, what is the digital display showing? If it's "dark", nothing displayed, then that is a clear indication the TS-820's PLL Unit has changed states from "Lock" to "Unlock". This is a simple test you can perform without removing any covers and it is a test your "certified Kenwood guru" should have asked you!

I forgot to mention that Butch also gave you good advice to confirm that Pins 8 and 9 jumper is installed in the External VFO socket on rear panel. Your manual shows this in Figure 4 around page 8. Your guru should have confirmed this.

If the black plug is missing you can use a piece of hook-up wire but not the best and must be correct gauge to make reliable contact as it is inserted into the socket. This jumper provides 9vdc regulated supply to your internal VFO.

Terry K9TW

Did he have the radio in his possession or was his confirmation based on talking you thru some form of testing?

You have been given good advice not to remove the covers and to obtain the operating and service manuals and start reading for starters..

I would suggest that since you want to just listen at this time to make sure that the Send/Receive switch is placed in Receive and left there, the CAR level control is set full CCW, and that the Heater switch is left in the OFF position. This ensures that there is no way to have any unintentional transmit that could damage your final tubes.

Read the operating manual and familiarize yourself with the controls. Then pre-set all the controls for Receive mode as listed under Section 4.2 Receiver Tuning Table 1.

One test you can do that will tell you something about the Coil Pack and RF and IFT alignment is:

1. Set the VFO to approx 200 (Band switch at 14mhz)
2. Set the Drive Control to 1200
3. Set the RF Gain to Full CW or max open (AF gain to comfortable level)
4. Set the Function Switch to 25khz (Marker or Crystal calibrator on)
5. Tune the VFO around 200 until you hear the Marker signal
6. Peak the Marker signal using the Drive Control (peak = max deflection on S meter)
7. Should see approx S9 indication on the S-meter
8. Repeat this procedure on each band.

If you can peak the Marker signal on each band to approx S9 you know that the receiver RF and IF stages are functioning and alignment is pretty good. The rig should be able to copy off air signals.

Make sure you turn off Marker when done.

As someone mentioned connect as much wire as you can to the SO-239 antenna connector on rear of rig (single lead inserted into the center will work). Wont work as well as resonant dipole, but should be able to copy off air signals. Probably listen on 40 meters for starters.

If that works then suggest you put up a 40 meter dipole or inverted Vee as high as you can for starters. Will receive much better than piece of wire strung around perimeter of your room.

If you get no Maker signal or very low Marker signal, you need hands on help from a "certified" Kenwood guru. Not sure what that means, but can get the help here but will be slow and tedious to talk you thru tests and repairs. Local club may produce and Elmer?

Hello to all,

I have recently purchased one of these units. Unfortunately the seller did not disclose that it does not receive. My certified Kenwood repair guru confirmed this. The unit does get power, the internal speaker hisses but otherwise I cannot tell what works and what doesn't. I do not have a microphone yet (mainly because I have no license yet and wanted to figure out the workings of the radio and to listen to the world) so transmitting wasn't an issue but I'll want to try it sometime.

So, I am wondering if anyone has had to address the issue of not receiving and what steps anyone took to resolve said issue.

Now, please bear in mind that ham jargon is a foreign language to me. Plain English will be appreciated because I have no idea what any abbreviations mean.

Thanks in advance

Hi,
I suggest that you unscrew every screws holding the printed circuit board and retighten it securely. I mean all PCB's inside the radio and see what happens. Of course, you need to turn the radio off while you are doing the screw tightening.

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

Barry,

I mean no disrespect by what I am about to say.

If your knowledge of what you refer to as "ham jargon" which I assume is terms/phrases used in normal operation of your TS-820/ham equipment and electronic troubleshooting discussions, is non-existent, then you are going to have a very difficult time understanding and performing various tasks, even when stated in "Plain English", that will be asked of you.

One of the biggest misconceptions hams or people who want to be hams have is, especially those people/hams who's level of knowledge/skills and experience is either very low or non-existent, they believe for some odd reason they can learn all they need to know to fix their complex Kenwood hybrid by simply asking some questions of those who know more than they do. That's ludicrous thinking Barry. You can't gain the knowledge, experience, and skills necessary to properly and "safely" troubleshooting and repair you Kenwood TS-820 transceiver, over night, over a weekend, or even in 6 months. It takes time, a lot of time studying. In short, you can't learn it all by asking a few questions.

There are voltages inside the TS-820 that can easily kill you! You also must have experience using test equipment and skills using the test equipment when working around and measuring high voltage. Without those skills and experience, the chances of you damaging your TS-820, the test equipment, even yourself, is very high.

You didn't say whether the operator's manual came with your TS-820? If it didn't, that should have been the first thing you obtained and thoroughly read AND understood what you read, BEFORE you plugged the 820 into the wall outlet and powered it up! Too many people ignore this simple but very important and necessary step.

All the talk about tuners reminded me - I've got a Kenwood AT-200 tuner in great shape that I am thinking about selling. At least an 8 out of 10 for looks and performance. Christmas is coming and I need to sell some stuff! $195 plus $20 shipping in the continental US. If nobody's interested it might go up on ebay sometime soon. There's one way over $200 selling right now.

I've got a Washburn Idol Pro like brand new with box and tags (played very little) that I need to sell since I just bought a new guitar, too...

Hello everybody KB3WBT here
I just came downstairs from the net, I talked to Mark about those "plastic rivets" for the side-door on TS-520 (and other places)
I found a nylon replacement, at my local Lowes store, they fit right, only difference, you have to screw them in, instead of pushing, (just don't over-tighten) but looks good, and works perfect!
The price is also ok, $1 and some change for a pair.
I'm adding some pictures, hope you don't mind that the one is of another brand radio, but same function

Lars

45920. TS-820S ATTenuator question

I just picked up my first TS-820s at the Fort Wayne hamfest today. Its in great cosmetic shape. It had not been used for awhile. Inside it is pristine and it appears that it is in original "unmolested" condition. The owner stated that it had "issues" and described them as "low receive" and intermittent frequency display. The display works OK some times and I believe it to probably be a dirty contact causing it. No problem there. The real issue is that the ATT switch is pushed in and melted. Close examination is that the green and orange wires are fine. Those wires are part of the circuit to work the light at the top of the display. The bad part is there are two gray shielded wires and two resistors on the other side of the switch. They are burned beyond recognition. I have removed the switch to ready for replacement.

I downloaded the schematics and service manual for the TS-820S. I can find on the diagram the light circuit. I figure the other melted circuit probably controls the front end gain somehow. I can't seem to locate where on the schematic it is shown. I imagine there will be some other components that will need replacing as I dig in to be sure. I just need to find the circuit on the schematic.

Just to be clear on my experience, I have experience working with the TS-520 series. Having restored more than a dozen so far. This is my first 820.

Sorry for the long intro. Any help will be appreciated. BTW is this a common problem on the 820?

Thanks,
Tim

I saw you carrying it to the door! I was a little disappointed as this hamfest gets smaller every year. Probably my last year to attend.

The RF attenuator switch S8 is just to the left of the Relay unit board. You will see it uses a 470 ohm and 56 ohm voltage divider. Another deck is used to illuminate a LED to tell you that you have the RF atten on.

If these resistors are burned up I would be concerned that this unit experienced accidental transmit RF. With off air signals should be no way to burn anything up on this switch.

It would not be common to have any damage to this switch. You can just connect the two mini coax cables together to see if you have good receive sensitivity. Marker signal should be approx S9 if rig is functioning per design and aligned.

May need to lift the 9vdc off S8-2 to make sure it is not shorted.

Have checked all pots, connectors, untightened and retightened all boards, checked relays...still the same. There is one thing concerning the marker signal. It is very strong on WWV/JJY and in fact that band is quite sensitive. The rest of the bands peaked out with the drive are low on sensitivity. The radio is indeed receiving stations but a signal that would be S20 is more like an S5. Not sure if that points to a direction.

Subject: [TS-520_820_530_830] RE: RE: TS-520S Low Sensitivity On All Bands

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady

tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

73 Jim, N7JS

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <geekorama@...> wrote:

Just purchased a "working" 520S on Ebay....here we go! This radio did take one hell of a beating...arrived with the cooling fan smashed in as well as 2 corners. I worked out the difference with the seller. In the mean time, it actually does turn on, transmits, receives normal volume static out of speaker, all switches and knobs act normal, BUT the sensitivity is low on all bands. I can hear stations but they are way below what they should be.
I've done the obvious, RF Gain check, alignment, Voltages. Then I've looked for loose wires especially on the Fix Channel board and Function switch...nothing I can find. In addition: the calibrator signal is very sick...sounds like a Walrus in the distance every 25 Khz. You still do need to adjust the drive to hear it as well as other stations. Could someone point me in a direction. Is a diode or transistor the next culprit? I'm just still thinking something got knocked loose. Any help would be appreciated.

Topic: 45893 Message: 45923

Hello Everyone,

Since I am the new "Kid" here, I guess I needed to sort of introduce myself. I apologize for not doing so.
I sincerely hope that I am not stepping on anyone's toes. If you ever meet me you'll find that I speak my mind. I grew up in a time where you speak straight to the point and being "PC" was how a politician conduced business, usually right before you found out you should have voted for the other person. I still firmly believe that "NOTA" should be a valid vote on any ballot (None of the above-that party member now has 30 days to clean out their desk).

First, I want to thank everyone for replying to my query. To me, all of you are just a small yet valuable number of the "elmers" that some of you mention because the knowledge that you have far exceeds mine and it is that experience that I hope to reach out to from time to time. I hope that you will nurse me through my learning periods as someone almost certainly did the same for you.

Second, I am not afraid of a challenge. I purchased my radio because of reading reviews provided by folks like yourselves who have stated that the 820 was/is a great radio. I knew going in that It was old but still functional, just like many of you. And that maintaining the unit would be a cool way of learning about the older radios and the whole ham atmosphere. Kind of like why your wives decided to marry you despite knowing you. ;)

Third, Any and all actions I have taken with my radio was done AFTER I consulted with folks that actually have or had an 820. I downloaded (and consulted by the way) all the pertinent manuals that I could find because this unit did not come with any of any kind. I have further obtained books/manuals on getting my license, how to build antennas, how to have proper radio manners and etiquette and how to log contacts and on and on and on. I had already found my local ham club and am in contact with this group of VERY experienced operators. In fact, some of them look like Santa's Dad. I have, in the past, been one of those booger eating morons that has grabbed the wrong portion of the electronic device and reaped the benefits. I also pulled the plug wire off of my running car (a 1965 mustang that I sold) and found myself lying on the ground. Needless to say I no longer play with the electrical portions of my stuff, my radio nor my life.

Fourth, after taking my set to a certified Kenwood repair shop and letting the tech (who, by the way had an 820 as a young adult) has confirmed that it just plain ol' will not receive. He is troubleshooting and I am awaiting his findings. I have contacted the seller and we are communicating.

For those of you that specifically addressed my query and offered tips and suggestions on how to help, you are the folks I am most grateful to. From this interaction I believe that you will be willing to help anyone at any turn. I look forward to reaching out to you in the future.

Barry Brown
Lexington, KY

No, not the one in SC. He has been doing a SUPERB job at mentoring me.
My words are my own.

Thanks for the reply. I finally found the rest of the switch on the schematic. It appears to be connected at the antenna input to the coil pack. I agree with you 100%. Looks to me that someone transmitted INTO the rig. Maybe a crossed coax connection. I fear that the input winding on the first coil may be damaged. Got too tired last night to check. That will be the first thing this morning. I am now looking for a replacement switch.

The filter caps are going bad and they will be replaced. Like I said in my first post, its VERY clean and fixing it will be a joy.

Well if that has occurred then L8 step up xfmr and L24/L25 8.830mhz wave traps are suspect as well. These are not available. Have to ask here if anyone has any that they can harvest from junk board or check with Bob Mansker to see if he has a Coil Pack Board. Accidental RF usually stops at Q2 RF amp and can buy sub replacements for it.

Can use Marker signal or better yet RF Sig gen to troubleshoot this to confirm what is bad and not just assume these components in the signal path are hurt.

Hopefully RF attenuator acted like a fuse?

May need to lift the 9vdc off S8-2 to make sure it is not shorted.

I just picked up my first TS-820s at the Fort Wayne hamfest today. Its in great cosmetic shape. It had not been used for awhile. Inside it is pristine and it appears that it is in original "unmolested" condition. The owner stated that it had "issues" and described them as "low receive" and intermittent frequency display. The display works OK some times and I believe it to probably be a dirty contact causing it. No problem there. The real issue is that the ATT switch is pushed in and melted. Close examination is that the green and orange wires are fine. Those wires are part of the circuit to work the light at the top of the display. The bad part is there are two gray shielded wires and two resistors on the other side of the switch. They are burned beyond recognition. I have removed the switch to ready for replacement.

I downloaded the schematics and service manual for the TS-820S. I can find on the diagram the light circuit. I figure the other melted circuit probably controls the front end gain somehow. I can't seem to locate where on the schematic it is shown. I imagine there will be some other components that will need replacing as I dig in to be sure. I just need to find the circuit on the schematic.

Just to be clear on my experience, I have experience working with the TS-520 series. Having restored more than a dozen so far. This is my first 820.

Sorry for the long intro. Any help will be appreciated. BTW is this a common problem on the 820?

Thanks,
Tim

WWV uses different RF Amp and Mixer. The good thing is it tells you that everything from the BPF on was not damaged in the dropping/damage incident.

It also tells you that the TR relay contacts are good, the Rec Ant switch is good, the Xverter switch is good, and the RF Attenuator switch is good.

It tells you where to start signal injection for troubleshooting.

Do you have a RF Signal Generator of any kind? If so can find where attenuation is occurring in about 10 minutes by injecting test signal starting at ANT and RFG. For example if you inject at RFG and signal is weak and then inject at MD and signal is good you know problem is at Q3 RF amp stage. You then perform DC voltages (DSG) at Q3. I dont think Q3 is bad as dual gate mosfets typically dont get weak. Either good or bad and a dropping incident should not damage them.

Absent a signal generator it will be very hard to troubleshoot.

Only other thing I can think of is.....Are Q3 RF amp and Q2 Mixer mosfets on the RF Board in sockets? I cant remember if they are or not. If they are then you could try with power off un-plugginig and re-seating them.making sure not to rotate and cross the leads.

Any kind of RF Sig gen will work for troubleshooting. You dont need an accurate RF output level just a source of RF for injection.

Have checked all pots, connectors, untightened and retightened all boards, checked relays...still the same. There is one thing concerning the marker signal. It is very strong on WWV/JJY and in fact that band is quite sensitive. The rest of the bands peaked out with the drive are low on sensitivity. The radio is indeed receiving stations but a signal that would be S20 is more like an S5. Not sure if that points to a direction.

Subject: [TS-520_820_530_830] RE: RE: TS-520S Low Sensitivity On All Bands

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

73 Jim, N7JS

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <geekorama@...> wrote:

Just purchased a "working" 520S on Ebay....here we go! This radio did take one hell of a beating...arrived with the cooling fan smashed in as well as 2 corners. I worked out the difference with the seller. In the mean time, it actually does turn on, transmits, receives normal volume static out of speaker, all switches and knobs act normal, BUT the sensitivity is low on all bands. I can hear stations but they are way below what they should be.
I've done the obvious, RF Gain check, alignment, Voltages. Then I've looked for loose wires especially on the Fix Channel board and Function switch...nothing I can find. In addition:

the calibrator signal is very sick...sounds like a Walrus in the distance every 25 Khz. You still do need to adjust the drive to hear it as well as other stations. Could someone point me in a direction. Is a diode or transistor the next culprit? I'm just still thinking something got knocked loose. Any help would be appreciated.

Barry

In your very first post you said you had a new to you TS820 that did not receive and your Kenwood guru said "Yep it does not receive". So to me that means he eliminated Operator error (which surely does occur with all of us). You then went on to ask what could cause no receive and oh by the way please explain it to me without using proper rig specific and fundamental radio electronic terminology ie jargon.

If you seriously reflect on that you should see it was a silly request. Like me saying my car will not start and asking on an Auto forum what could be the cause.

No receive in a Kenwood Hybrid could be a myriad of reasons. Same as my car not starting. It requires numerous follow up questions like does it try to start, is it turning over, does it crank, does solenoid chatter, does it fire and stall......etc.

All Mike is trying to tell you is that with this medium we are limited to Telling (in written form only). We cannot Show, We cannot Observe, and We cannot Demonstrate to you. It is a very laborious process even helping a more experienced person who has the fundamental knowledge, experience, tools and test equipment.

Troubleshooting a Kenwood Hybrid requires a way of Thinking. It starts with analyzing the symptoms, studying the schematics, applying test equipment, and analyzing the test results.

Yes you can come here and get the "experiential based" stuff and that is what most members will first feed back to you. Such as is the 8 to 9 jumper installed,or is the Digital display illuminated, or wiggle all connectors or tighten all board grounding screws. After those are exhausted then you have to put on thinking cap and troubleshoot and that requires understanding of basic SSB receiver/transmitter, how to read a schematic, a minimum amount of test gear and knowing how to use it.

Lastly, when someone ask a question like you did on your initial post the Alarm Bells all sound off. We cannot in good conscience direct you to take covers off and start wiggling connectors and tightening board screws without a stern warning about the safety risks and how to manage those hazards.

So it appears the rig is now with the Kenwood tech which is best at this stage of your development.

I have to go now and Google on which is the best single engine airplane for me to buy and then I will buy a 40 year old Cessna or Piper Cub and then I will read the operating manual and then I will join a Yahoo Cessna forum and ask for help on how to get it started and keep it running without stalling and please dont respond using any of that airplane jargon like Yaw or Artificial Horizon or Attitude Director Indicator or Manifold temperature or .....!!!

Sounds silly doesnt it, but same thing you did and many new members do. Where would an experienced Cessna or Piper Cub "expert" on the forum begin to answer my question?

So dont be surprised if you get some admonishment in the future and dont feel offended or dissed. People mean no disrespect.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <airwolff@...> wrote:

Hello Everyone,

Since I am the new "Kid" here, I guess I needed to sort of introduce myself. I apologize for not doing so.
I sincerely hope that I am not stepping on anyone's toes. If you ever meet me you'll find that I speak my mind. I grew up in a time where you speak straight to the point and being "PC" was how a politician conduced business, usually right before you found out you should have voted for the other person. I still firmly believe that "NOTA" should be a valid vote on any ballot (None of the above-that party member now has 30 days to clean out their desk).

First, I want to thank everyone for replying to my query. To me, all of you are just a small yet valuable number of the "elmers" that some of you mention because the knowledge that you have far exceeds mine and it is that experience that I hope to reach out to from time to time. I hope that you will nurse me through my learning periods as someone almost certainly did the same for you.

Second, I am not afraid of a challenge. I purchased my radio because of reading reviews provided by folks like yourselves who have stated that the 820 was/is a great radio. I knew going in that It was old but still functional, just like many of you. And that maintaining the unit would be a cool way of learning about the older radios and the whole ham atmosphere. Kind of like why your wives decided to marry you despite knowing you. ;)

Third, Any and all actions I have taken with my radio was done AFTER I consulted with folks that actually have or had an 820. I downloaded (and consulted by the way) all the pertinent manuals that I could find because this unit did not come with any of any kind. I have further obtained books/manuals on getting my license, how to build antennas, how to have proper radio manners and etiquette and how to log contacts and on and on and on. I had already found my local ham club and am in contact with this group of VERY experienced operators. In fact, some of them look like Santa's Dad. I have, in the past, been one of those booger eating morons that has grabbed the wrong portion of the electronic device and reaped the benefits. I also pulled the plug wire off of my running car (a 1965 mustang that I sold) and found myself lying on the ground. Needless to say I no longer play with the electrical portions of my stuff, my radio nor my life.

Fourth, after taking my set to a certified Kenwood repair shop and letting the tech (who, by the way had an 820 as a young adult) has confirmed that it just plain ol' will not receive. He is troubleshooting and I am awaiting his findings. I have contacted the seller and we are communicating.

For those of you that specifically addressed my query and offered tips and suggestions on how to help, you are the folks I am most grateful to. From this interaction I believe that you will be willing to help anyone at any turn. I look forward to reaching out to you in the future.

Barry Brown

Hi Terry,

Thanks for the info. I'm feeling better that this radio can certainly be fixed without major headache. I have a ham friend with an RF Signal Generator so we will begin to trace this issue until found based on your suggestions and then going from there. Yes, there were actually 3 transistor/mosfets in sockets on the RF deck and I did the pull and re-seat without change.

I'll give update.

45930. TS520S low receive and no RF output or plate current

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-17 18:42:42 UTC
From: <lonelyone_64109@...>
Topic: 45930 Message: 45930

I have a TS520S that the cathode and screen resistors were burned up due to being overdriven.(the owner turned up something when his friends on the air said he was really weak). I've replaced the resistors as well as the 470 ohm resistors in the 210 and 300 volt supplies. I also replaced the caps and RF choke in the final cage as per K4EAA. Prior to installing the tubes I checked the voltages and the HV was 933, the 210 read 256, and the 300 supply read 344 (all were no load values). I installed the tubes and the receive is very low. The S-meter reads S-2 in receive but does drop to zero in transmit. All bands are working as I can hear the phone stations running the sweepstakes this weekend. The crystal calibrator works fine and the signal lever from it is around S-5 to S-9 depending on the band.

I plugged in a microphone and the rig works in VOX as well as PTT and the ALC position on the meter reads fine. I am not showing any plate bias current on the meter when in transmit but but I do have the HV reading on the meter when I switch to transmit.

I am wondering if i missed something that may have gotten burnt or has opened up. With the exception of the receive and no output the radio is working just fine. Any help would be appreciated.

Paul WB0CJB

45931. Re: [TS-520_820_530_830] TS520S low receive and no RF output or plate current

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-17 19:13:37 UTC
From: Mike
Topic: 45930 Message: 45931

Paul,

You said the ALC meter position works fine. Are you saying that in TUNE mode with the meter switch set to ALC and the transmitter keyed with the SEND switch, adjusting the DRIVE control produces ALC meter indication? You also said there is no 60ma idling current with the transmitter keyed with PTT in LSB or USB, is that correct? If both answers are "yes" then you need to check the rear panel's "SG" switch to ensure it is in the "ON" Position. Quite often when handling the transceiver this switch gets slide, accidentally, into the "OFF" position. When that occurs there will be no 60ma idling current indicated on the meter (meter switch set to IP) when the transmitter is keyed in LSB or USB.

Forgot to mentioned. If the SG switch is, in fact, in the "OFF" position
there will be no RF output, regardless of the mode.

Topic: 45920 Message: 45933

I know that I am an "old timer", but I do get puzzled when members
appear to consider junking a Kenwood simply because a coil is no longer
available.
Some thing like the IF trap coil can be wound in a few seconds sealed
with Supaglue or nail varnish and installed. Often the size of wire and
number of turns can be seen by inspection.
But given a signal generator and VTVM or Oscilloscope, or even a good
old GDO it is a simple matter to make new RF coils.
Now I am retired I am a semi professional radio restorer admittedly, but
I have been winding my own coils for over 60 years.
It you want a REAL tough job, try rewinding the RF Chokes in a 1970's
Marconi signal generator (100mH) each about 550 turns of hair thin #44
wire on a tiny former. That really is hard to do!!!
Radios of the age of the Kenwood hybrids really need quite a lot of
knowledge and some test gear to keep going and to fix. They are NOT
appropriate for "appliance operators".

I checked the SG switch and it is on. When I have the radio in the USB or LSB position and speak into the microphone I get a normal ALC deflection with the meter in the ALC position. With the meter in the Ip or RF output position I do not see any movement. Also when I put the rig in the tune position and try to adjust the drive control through its range I do not get any ALC, Ip or RF output indication at all, . The same goes for the 60 mA plate idling current. Thinking it MIGHT be the metering circuit I even put a wattmeter in line with the dummy load but again no power output. I need to go through and check the voltages on the final board, the RF board, and possibly the IF board. I also have a service bulletin reprint saying to check the -6V source as it could also cause low receive and no TX output. But due to my work schedule it will be Thursday evening before I can get any time to further look into this problem. Since there were several resistors burned up i am thinking there is one that I have not found that is open and is causing the lack of RF output and meter indications.

Paul,

You said the ALC meter position works fine. Are you saying that in TUNE mode with the meter switch set to ALC and the transmitter keyed with the SEND switch, adjusting the DRIVE control produces ALC meter indication? You also said there is no 60ma idling current with the transmitter keyed with PTT in LSB or USB, is that correct? If both answers are "yes" then you need to check the rear panel's "SG" switch to ensure it is in the "ON" Position. Quite often when handling the transceiver this switch gets slide, accidentally, into the "OFF" position. When that occurs there will be no 60ma idling current indicated on the meter (meter switch set to IP) when the transmitter is keyed in LSB or USB.

45936. Kenwood Hybrid Net Update (November 17, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-18 04:20:10 UTC
From: Mark Gilger
Topic: 45936 Message: 45936

The Saturday net we had 15 check-in with good
band conditions. There were 2 new check ins,
KD8PFN, and W8NIC. We had the following number of radios checking in.

7 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
2 running TS-830S

I was running my TS-940s.

The Sunday□s 20 meter net had 5 stations checking
in under poor band conditions. The SS SSB contest
was on, so I image a lot of regulars were pulled away for that.

Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S

I was running my TS-940s.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo

mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54
October 2013, Saturday☐s net total = 61, Sunday☐s total = 55
November 2013, Saturday☐s net total = 51, Sunday☐s total = 42 (Month to date)

Didn't we just have someone recently who had "the SG switch and it is on" but turns out that the SG switch was the thing that was BROKEN?

Can you check the actual switch itself? Power off, lift a wire, check continuity? Or take a voltage reading across the switch with power on, proper precautions? If there is voltage shown on a meter across the switch when it is in both positions, then it isn't actually working.

If the reading drops to zero when the switch is in the "On" position, and up to some value in the "Off" position, then it's good. FROM MY FAULTY MEMORY ONLY! This should be around 210 - 240 VDC...

(Please correct this value if it's wrong, someone. It's the middle of a pain-filled and sleepless night for me and I don't have a schematic or service manual handy on this little laptop I use for email and such.)

Will is exactly correct.

First thing I would check is SG voltage at the 6146 tube socket pin.

Think about what you are seeing.

If you get ALC indication in SSB mode when modulating the rig you have proved that:

1. There is Carrier at the Balanced Modulator
2. That you are producing a TIF output from IF board to RF board
3. That you have RF drive from the TX Mixer
4. That you have RF drive from the Driver tube
5. That you have RF drive level in excess of the operating bias on the 6146 finals
6. That the ALC transistor is being biased on with 6146 positive grid current flows on voice peaks.
7. That the ALC bus voltage is being pulled down
8. That the S-meter sees the ALC bus voltage going down and is driving the meter up scale.

OK with no RF output what are you missing? What do you need?

1. Screen grid voltage
2. Anode voltage
3. Plate current

6146 finals have to have filament voltage and emission as you have positive grid current. So tubes appear OK

You are missing is 6146 final tube plate current. Most likely cause is no Screen Grid voltage.

Start at the tube socket and work way back to HV rect board.

45940. Re: [TS-520_820_530_830] RE: TS520S low receive and no RF output or plate current

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-18 14:05:51 UTC
From: Mike
Topic: 45930 Message: 45940

Paul,

You also might want to watch my video on the 520/820 cathode circuit.
The video can be found at the following link:

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/TS520%20and%20TS-820%20Cathode%20circuit%20calculations.wmv

My video assumes the cathode resistors are 10 ohms each, not 9 or 11 ohms and the meter multiplier resistor is 3.3K. Actual cathode and meter multiplier resistor values will not be exactly 10 ohms and not be exactly 3.3K.

You can use different values of cathode current, such as 60ma for example, to determine what the cathode voltage will be then use the cathode voltage to determine what the voltage applied to the meter will be. Not all meters have the same exact internal resistance. I used the resistance values indicated in the video to keep the math simple, actual resistance values will be slightly different.

45941. RE: TS-820S ATTenuator question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-18 14:38:50 UTC
From: <tjb813@...>
Topic: 45920 Message: 45941

I guess I didn't read where anyone was "junking" a Kenwood. Maybe I missed a post. I have been fixing tube and hybrid radios for 35+ years. None of my equipment is "new". My hobby is restoration of Hallicrafters, Drakes, Kenwood Hybrids and Heathkits. I have a complete home brewed (by me) 1kw am station. Hand wound coils and all. If that makes me an "appliance" operator, gee, I appologise. I find that when an "inexperienced" person wants to learn about their equipment by doing repairs, I encourage the effort. The level of repair (board replacement or component level) is based on their level of comfort in making the repair, money available, or time. Now, on to the TS-820 fixing.....

Further investigation showed that the 56 ohm resistor became a "sink" for the RF current. The input coil and Q2 are fine. I had a similar switch in my junque box where all I had to do was swap the mounting bracket. Fixed the switch, new resistors and the receive is full blast 9+ with calibrator. Transmitter works great 100+ watts on all bands. Worked a few station in the sweepstakes this weekend with it.

Now, the next problem: The display is somewhat flaky. When first turned on it displays perfectly. After 5 minutes the most significant digit starts to flicker, then go out. The radioworks fine and the rest of the digits work correctly. Turning the radio off, then back on corrects the problem for awhile. I disassembled the DG1 and using my ESR meter, I think that the filter caps for HV supply for the display tube MAY be questionable. I will replace them tonight and see if that helps. I have not checked the LV supply on the AVR board.

Another symptom is that when I transmit in CW, the display gets real flaky and jumps all over. It works fine in USB and LSB. SAme symptoms on all bands. I suspect the digital board may have some solder issues.

Any input or experiences in this matter are welcome. Thanks
Tim

I am not familiar with any HV filter caps for the VFD in the Hybrids? There are no high voltages involved. VFD voltages are approx:

Filament = 4.0 to 5.0 vdc
Grids = -17.0 vdc to -19.0 vdc
Anode = +11 vdc to + 14 vdc

I think max voltage will be in the +22 vdc range from the DC to DC converter.

The VFD is seldom a problem. VFD power supply is seldom the problem.

Common problem is with the "vias" and plenty of folks here who have implemented the published fix for that. I think Mark Gilger would be good one to answer this.

I forgot to ask

With rig in Tune mode and trying to peak the ALC indication did you try with the CAR Level pot full CW and in all bands? If not do so.

Did you try in CW mode? If not do so but observe next sentence.

If you do this test do it quickly as the Tank circuit (Pi-network) will not likely be adjusted to resonance so will have high Plate current. Close the plates of the Plate Loading cap before you try to peak the ALC indication in CW mode.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <lonelyone_64109@...> wrote:

I checked the SG switch and it is on. When I have the radio in the USB or LSB position and speak into the microphone I get a normal ALC deflection with the meter in the ALC position. With the meter in the Ip or RF output position I do not see any movement. Also when I put the rig in the tune position and try to adjust the drive control through its range I do not get any ALC, Ip or RF output indication at all, . The same goes for the 60 mA plate idling current. Thinking it MIGHT be the metering circuit I even put a wattmeter in line with the dummy load but again no power output. I need to go through and check the voltages on the final board, the RF board, and possibly the IF board. I also have a service bulletin reprint saying to check the -6V source as it could also cause low receive and no TX output. But due to my work schedule it will be Thursday evening before I can get any time to further look into this problem. Since there were several resistors burned up i am thinking there is one that I have not found that is open and is causing the lack of RF output and meter indications.

On 11/17/2013 1:13 PM, Mike wrote:

Paul,

You said the ALC meter position works fine. Are you saying that in TUNE mode with the meter switch set to ALC and the transmitter keyed with the SEND switch, adjusting the DRIVE control produces ALC meter indication? You also said there is no 60ma idling current with the transmitter keyed with PTT in LSB or USB, is that correct? If both answers are "yes" then you need to check the rear panel's "SG" switch to ensure it is in the "ON" Position.

Quite often when handling the transceiver this switch gets slide, accidentally, into the "OFF" position. When that occurs there will be no 60ma idling current indicated on the meter (meter switch set to IP) when the transmitter is keyed in LSB or USB.

VERY STRONG ON WWV!!!

BINGO!

I have a TS-520 with the EXACT same problem!

It occurred right after I switched to WWV and back.

Problem was that the WWV switch was not switching back!

Cycling the WWV switch fixed it - but I can get it to repeat if I try.

I need to clean the WWV switch with some electronic contact cleaner and then lube it with a little LPS-1. Suggest you do likewise.

Good Luck!

Have checked all pots, connectors, untightened and retightened all boards, checked relays...still the same. There is one thing concerning the marker signal. It is very strong on WWV/JJY and in fact that band is quite sensitive. The rest of the bands peaked out with the drive are low on sensitivity. The radio is indeed receiving stations but a signal that would be S20 is more like an S5. Not sure if that points to a direction.

Subject: [TS-520_820_530_830] RE: RE: TS-520S Low Sensitivity On All Bands

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

73 Jim, N7JS

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <geekorama@...> wrote:

Just purchased a "working" 520S on Ebay....here we go! This radio did take one hell of a beating...arrived with the cooling fan smashed in as well as 2 corners. I worked out the difference with the seller. In the mean time, it actually does turn on, transmits, receives normal volume static out of speaker, all switches and knobs act normal, BUT the sensitivity is low on all bands. I can hear stations but they are way below what they should be.
I've done the obvious, RF Gain check, alignment, Voltages. Then I've looked for loose wires especially on the Fix Channel board and Function switch...nothing I can find. In addition: the calibrator signal is very sick...sounds like a Walrus in the distance every 25 Khz. You still do need to adjust the drive to hear it as well as other stations. Could someone point me in a direction. Is a diode or transistor the next culprit? I'm just still thinking something got knocked loose. Any help would be appreciated.

Hello there.
Would it be true to say that a TS-830s fitted with both the YK-88C filter and the YG-455CN filter would not work ?
The reason I ask is that my TS-830S has these fitted and I have had to bypass the YG-455CN due to it blocking all but high pitch sigs.

Perhaps I didn't make myself clear. I have owned a TS820S for several years and am pretty familiar with the unit by now. A poster appeared to imply that a Kenwood could only be repaired if the IF trap coil was available ex stock. Now this coil is a simple series tuned circuit at 8.3 odd MHz in the input. The sort of thing that could be wound in a minute or two.
It was the apparent inability to make such a simple component that struck me as an example of the need for good technical knowledge and access to test equipment as a
prerequisite for the maintenance and repair of older Ham gear.
There can be little hope of getting specialised parts for 40 year old equipment and it can only get worse over time.
I guess the fact that we have always had a "fix it" mentality in NZ due to our isolation makes
me even more inclined that way.

But the thought of someone who cannot even use a digital voltmeter (there have been some on this group) getting into a Kenwood hybrid is downright scary.

However from your post tjb813 you could never be called an "appliance operator", it is good to hear how much you have achieved. I got WAC back in 1974 with an
ALL home brew station running 100 watts to a TT21 final. That included TX, RX and antennas.
These days I do use some older commercial gear, but it is heavily modified and upgraded where possible.

The troubling thing to me though is that there seems to be a group of would be Kenwood Hybrid users whose knowledge is too incomplete to safely work on these sets.
"Board level" repairs can be quite tricky (a TS820 is NOT like a desktop computer) and access to working boards is often difficult or impossible.
Hope this clarifies things.

Blimey Mike!
You must have run into a lot of 'em over there.
It does seem though that the way exams are "organised" in the US makes
it far too
easy to memorise your way through.
Reminds me of a phenomenon we noticed in my many years at Auckland
university.
Asian students (especially those fluent in written Chinese) did VERY
well up to Bachelor
degree level. But had a very high failure rate when doing any post Grad
work.
It appears that being fluent in thousands of characters trains one to
have a photographic
memory. Works fine, until you have to work "outside the box".
One Chinese friend of mine was considered only an average student in
Malaysia, but got a PhD
and he reckoned it was because he didn't have a good one!!

Still, with the internet, I wonder what the attraction of Ham radio is
to someone with no
personal interest in electronics?
After all, hybrids may be cheap (mine cost me $40 (NZ), not working, 10
years ago) but there are kits available
which can get you on the air for only a hundred dollars or so.
If they can't build one of those then perhaps they are in the wrong
hobby I guess.

Perhaps we have to accept that we are becoming a bit of a relic?
After all, I was licensed as G3NIA when I was 17, I'm now 73, and I'm
still quite a "young" Ham.

Topic: 45920 Message: 45951

I am the one that advised the Op that his rig may have experienced a burned up L8 Ant Step Up transformer and perhaps damage to the two IF wave traps. I advised that he should contact Bob Mansker to see if he had a replacement L8 and if not to ask on the Forum if someone had a parts board that they could harvest from.

I stand by that counsel and totally disagree with you. For the average new licensee and new KW hybrid owner winding a Ant step-up and/or IF wave traps is not an easy undertaking.

To your sir I ask when is the last time you had a TS820 with a bad L8 on your bench? Have you ever removed L8 from a TS820 and removed the shield can and observed what it looks like after seeing 100 watts? I doubt it. I submit sir you would be hard pressed to rewind L8 without help from this Forum.

Perhaps if you were lucky you could get a remnant from it and mike it to determine the wire gauge. What is the turns ratio? What is the primary and secondary inductance? Does polarity matter? What direction do you wind? Can it be scramble wound? What winding goes on first? Can they overlap?

After rewinding what testing will you do to ensure it is correct before putting it on the board and re-installing the board? What frequency RF signal would you use? What signal levels would you use? What acceptance criteria?

More than one of our members have rewound L8 and L41 only to find they do not work after repeated attempts to get a good one. Have been plenty who also experienced glowing 6146 plates after incorrectly re-installing the RF board. I have a customers TS830 here now on bench with a bad L41 that an attempted rewind performed. The owner is a talented ham and experimenter who is doing Arduino and Picaxe work and automating antenna tuners etc, but soon realized rewinding Ant step ups was not his specialty.

If it was so damn easy most of the members would be routinely winding them. Is it possible? You bet it is. Gordon N6WK is our resident expert at it and he didnt get a good one first time out of the gate.

As to the parallel and series IF wave traps a little easier as you would at least be able to go to the schematic and see the capacitance values. What would a new person do with those values? How would they determine the needed inductance and number of turns required on an iron core?

You seem to forget that we are talking about new licensees who have just bought a KW Hybrid. At this stage of their development they lack the knowledge, experience, and the basic test gear needed to wind Ant step up xfmrs and IF wave traps. They likely dont even have soldering and de-soldering equipment or soldering experience at this point.

Looking at a burned up L8 or IF wave trap in their hand they would be faced with numerous challenges including:

They cannot measure the resistance (which is of little value to them). They cannot use an LCR bridge and measure winding inductance even if they had a bridge. They cannot disassemble and count turns. They cannot excite with RF Sig Gen and observe on RF millivolt meter or O-scope to determine resonant frequency, How would they configure the test set up? Would they use resistors or capacitors for coupling isolation and if so what values? Would it be a peak or a null they should look for? They cannot Grid Dip it and very likely never heard of a GDO!

To these newbies what LC ratio would you suggest they use? What wire gauge? How many turns on an iron core? To your way of thinking should be childs play for these new folks.

Of course you and I after 50 years in the hobby should be quite capable of winding parallel and series resonant wavetraps for 8.830mhz from scratch. I wont bore you with how I would do it.

So for the fellow with 35 years boat anchor repair experience if he needs and wants to rewind L8 Ant step-up transformer and/or his IF wave traps for his Fort Wayne Hamfest treasure I say have a ball. I will be glad to give him any assistance that he may need.

For the newbies who may be lucky if you own a DMM there is absolutely no shame in asking Bob Mansker or other forum members if they have a L8 or L41 of related wave traps. It makes you no less a ham as our friend here.

What it does do for you is you will have the factory correct parts in hand quickly and then just be faced with the challenge of board removal and installation and unsolder and resolder operation to restore you KW Hybrid to operation.

---In TS-520_820_530_830@yahoogroups.com, <c.c.wright@...> wrote:

Perhaps I didn't make myself clear. I have owned a TS820S for several
years and am pretty familiar with the unit by now. A poster appeared to
imply that a Kenwood could only be repaired if the IF trap coil was
available ex stock. Now this coil is a simple series tuned circuit at
8.3 odd MHz in the input. The sort of thing that could be wound in a
minute or two.
It was the apparent inability to make such a simple component that
struck me as an example of the need for good technical knowledge and
access to test equipment as a
prerequisite for the maintenance and repair of older Ham gear.
There can be little hope of getting specialised parts for 40 year old
equipment and it can only get worse over time.
I guess the fact that we have always had a "fix it" mentality in NZ due
to our isolation makes
me even more inclined that way.

But the thought of someone who cannot even use a digital voltmeter
(there have been some on this group) getting into a Kenwood hybrid is
downright scary.

However from your post tjb813 you could never be called an "appliance operator", it is good to hear how much you have achieved. I got WAC back in 1974 with an
ALL home brew station running 100 watts to a TT21 final. That included TX, RX and antennas.
These days I do use some older commercial gear, but it is heavily modified and upgraded where possible.

The troubling thing to me though is that there seems to be a group of would be Kenwood Hybrid users whose knowledge is too incomplete to safely work on these sets.
"Board level" repairs can be quite tricky (a TS820 is NOT like a desktop computer) and access to working boards is often difficult or impossible.
Hope this clarifies things.

John:

Look at your Instruction Manual at Fig 5.2. Kenwood recommends that you select the filter combination that allows you to maximize full range of the VBT function. That is accomplished with the Yk-88C and Yg-455C filters (the 1st CW4 position).

I have never understood using the narrow filters when you can get virtually same band width with the VBT control. Perhaps flipping mode switch is easier than varying a pot?

Terry K9TW

Welp, as usual these days, the reply was the first I (personally) saw of this request. Are there any other bits of this thread? Has anyone asked him if he has downloaded the DG-5 schematics and docs yet?

This thread is completely new to me, though. Is there more of it, as I sort of guess from Mark's response? I'd send him a link to the DG-5 docs, if no-one else already has. It's a starting place, anyway. But I don't want to duplicate someone else's posting and double up on information. Sometimes redundancy is just wasted electrons.

Welcome to the new Yahooligan "service."

I got, very early Saturday morning, a boat-load of week-, two-week-, and even a few three-week- old posts, all coming in out of order, will he or nil he; some came middle posts first, then the beginning of the thread, maybe even the end of the whole thing. Some of them I am pretty sure I didn't ever (yet, but there's always NEXT week, huh?) get all of the thread.

To make sense of it, I did a re-sort by-subject instead of the usual by-time that I use for everything else, and was able to follow most of them.

Can anyone claim DG-5 expertise? I've got one I'd like to get working, too... (Seems to work powered on the bench supply and not the radio, as a freq. counter. Plug it into the 520SE and the diodes in the low-voltage supply BURN, in seconds. Done it twice so far and NO the cables are pristine. (I have NOT plugged it into the radio for a third time!!) I'm hoping to open it up and start checking things out this week, if time and troubles permit.

At a guess, you'd alter the value of some resistor around the RIT control that feeds the RIT voltage in. I don't have a 530 manual around but on the 520 it appears to come from the FIX CH board - the diagram I have isn't very clear - and consists of a 5k pot and a voltage divider.

I can't help but think that an 8kHz spread on the RIT would be awfully twitchy though.

Topic: 45947 Message: 45958

Terry - hello.
It was looking at the Instruction Manual at Fig 5.2. where various combinations of filter are listed, that I saw that my TS-830S had a combination of two filters that are not on the Manual's list ! ("Kenwood recommends that you select the filter combination that allows you to maximize full range of the VBT function. That is accomplished with the Yk-88C and Yg-455C filters (the 1st CW4 position").
So I am assuming a previous owner fitted a wrong filter in the YG-455CN. (My TS-830S has a YK-88C & YG-455CN combination that doesn't work).
Anyway - the YK-88C 500Hz filter on its own [CW2 position] works fine HI
Mind you - I would be interested to hear from anyone who has this combination of filters that DOES work. That would suggest I may have a faulty YG-455CN filter.

A couple of month ago I received a TS520 for FREE.. nice of cousre.
The endtubes were a 6146A an a 6146B. So I swapped them with 2 6146B's from my old TS520SE.
here it comes.

1. I cannot neutralize thePA. I have connected a VTVM AND a rf probe to the set and followed the manual precisely.. But I have turned the TC1 neutralize cap 260 degrees. but no change in deflection of the connected meters... The set is working FB however. But the deip in Ip is not coniciding with the max RF output. .

2. The set is quite deaf on 1.8 en 3.5 Mhz just a loud hiss... when i use a crystal oscillator in the vicinity I do hear the freq of the xtal though.... but a HAM nearby I cannot hear on 80 meters.... Is that just a matter of re-alignment ?? the rest of the band are receiving FB.
I have attached a end fed halve wave for 20 mtrs. so I can only tx on 20 and 10 meter

Tks

Wally/PA3BTT

Sorry to say, I still cannot agree at all.
They are simple solenoid wound coils of only a few turns. To potentially
"junk"
a hybrid simply because they have been damaged would be a crying shame!
I have to "stand to my guns" on this debate, if you have so little
knowledge of
electronics that you can't wind a coil (something I have been doing
since the age of 9!)
then you literally have no business inside a Kenwood hybrid.
If you want to repair one anyway, then you will need expert practical
help, paid or
unpaid. That might easily defeat the "hybrid as a cheap option", case.

You may be replying to the wrong post, sir!

I didn't notice anyone "junking" anything. But, if winding coils makes you an electronics "expert" then I bow to your superior intellect. LOL

It's the "self proclaimed" experts like you that discourage people from learning and from posting novice, learning questions. You obviously have lost sight of what this list is truly about. Helping and sharing with those with common interests.

Lets see a FEW turns?

L25 uses a 100 pf cap. That means to resonate that at 8.830mhz you need approx 3,25 uhy choke coil. Assuming a bobbin of 0.125 inch diameter and 0.250 inch high then 50 turns is approx 3.25 uhy. So if 50 turns on an air wound core how many turns would that be on a ferrite core? The answer would escape many KW hybrid owners new and old alike.

I once read on QRZ a fellow like you telling people it was easy to wind plate chokes for 1KW linears. He had been doing it his way for years. Just wind a bunch of turns and if it burns up wind another. Not to worry about the fireworks. He posted this after a new member was asking how to determine the parallel resonance and series resonance holes and what test gear would he need. He had a GDO but was having trouble finding the series resonant holes. He did not understand he needed to place short jumper across the choke windings and why he needed to do that. The old timer obviously had no clue as well. Your advice reminds me of that old timer. Just throw a few turns on it.

Your problem is you apparently cant or do not read and you cant get past the fact that people enter the hobby in very different way today than they did 60 years ago. They were not winding coils since age 9. Through no fault of their own they enter under todays process and it is very easy to see why they would buy a KW hybrid as their first rig....reputation, economics, and availability.

I dont know why you got fixated on wave traps and overlooked ant step up xfmr L8. Maybe pining for those days when you were 9 years old? It doesnt matter.

I will waste the key strokes one last time:

I DID NOT TELL ANYONE TO JUNK A HYBRID. THE OP DID NOT SAY HE WAS GOING TO JUNK A HYBRID.

IT IS FAR SIMPLER FOR THE AVERAGE KW HYBRID OWNER TO INSTALL A COIL PACK L8 OR L24 OR L25 FROM A PULLED BOARD THAN TO ATTEMPT TO REWIND THEM. AFTER YOU REWIND YOUR FIRST L8 OR L41 YOU WILL UNDERSTAND.

YES REWINDING CAN BE DONE IF NO ORIGINALS CAN BE HAD.

For those members who do not know, each message a member post should have their "name" or "call sign" as a signature. Abbreviated names such as "gigawatt900" or "willynilly900" are not acceptable signature names. Abbreviated names are only acceptable as part of your email address, not as a signature to your messages posted on the group server.

While there are a lot of members who do not have the technical knowledge, experience, and skills to properly and safely troubleshoot their KW hybrids, if there are members who deem it necessary to discuss these subject(s) with other members, please conduct your discussions about these subjects off group, through private email. If a member has a disagreement about a technical troubleshooting process such as what component in the final amplifier is causing loss of IP current, those discussions are acceptable on the group but in a respectful manner.

Thanks and 73
Mike W5RKL

I've been real lucky and brought 3 of them back
by sticking wires through all of the plated
through holes on the one board that has all of
the logic chips on it, and resoldering. At the
same time making sure all of the grounds are
cleaned on the corner of each pcb. I had to do
this on two TS-820's and my R820. So far, still
working. Knock on wood.....

>> HI GROUP IAM WORKING ON A DG-5 THAT DOES NOT LITE
UP AT ALL D-18 HAS

Welp, as usual these days, the reply
was the first I (personally) saw of

this request. Are there any other bits of this thread? Has
anyone

asked him if he has downloaded the DG-5 schematics and docs
yet?

This thread is completely new to me, though. Is there more
of it, as I

sort of guess from Mark's response? I'd send him a
link to the DG-5

docs, if no-one else already has. It's a starting
place, anyway. But I

don't want to duplicate someone else's posting and
double up on

information. Sometimes redundancy is just wasted
electrons.

Welcome to the new Yahooligan "service."

I got, very early Saturday morning, a boat-load of week-,
two-week-, and

even a few three-week- old posts, all coming in out of
order, will he or

nil he; some came middle posts first, then the beginning of
the thread,

maybe even the end of the whole thing. Some of them I am
pretty sure I

didn't ever (yet, but there's always NEXT week,
huh?) get all of the thread.

To make sense of it, I did a re-sort by-subject instead of
the usual

by-time that I use for everything else, and was able to
follow most of them.

Can anyone claim DG-5 expertise? I've got one I'd
like to get working,

too... (Seems to work powered on the bench supply and not
the radio, as

a freq. counter. Plug it into the 520SE and the diodes in
the

low-voltage supply BURN, in seconds. Done it twice so far
and NO the

cables are pristine. (I have NOT plugged it into the radio
for a third

time!!) I'm hoping to open it up and start checking
things out this

week, if time and troubles permit.

From: <tjb813@...>
Topic: 45920 Message: 45969

Agreed. Well, getting past the QRN........

as I said in a previous post, the input coils were not damaged and the receive is right on. So I went on to figure out why the most significant digit of the display was fading in and out.

I did some research on the DG-1. Figured the problem with the fading digit was the grid driver for the MSD or the decimal decoder 3442 chip. Then a quick check with scope indicated lack of base drive on the driver transistor. THe 3442 became the prime suspect. So I re-soldered the chip and Voila, it works perfect. So not to be foolish, I re-soldered ALL of the plated through holes for ALL the chips and pass thru holes. So that problem is now fixed. I am liking this 820 more and more.

Now the last known problem is tricky. On receive the display works perfect on all bands and modes. In transmit it works perfect in USB and LSB modes, but, in CW and FSK, it jumps up approximately 5 MHz and is fluttering around. I am searching the manual and schematics to determine how the display compensates for CW offset as the actual receive displayed frequency would be different from the transmit display frequency by the cw tone (approx 600Hz or so). The DG-5 for the 520 does not compensate for that and can be an annoyance.

I read in the service manual about testing and adjusting the input signal levels for the counter. Looks like a good place to start with the scope to see if I am getting the correct levels in transmit. I will assume at first that the DG-1 is not at fault, and look at the carrier boards. So, more fun tonight digging in.

Lets see a FEW turns?

L25 uses a 100 pf cap. That means to resonate that at 8.830mhz you need approx 3,25 uhy choke coil. Assuming a bobbin of 0.125 inch diameter and 0.250 inch high then 50 turns is approx 3.25 uhy. So if 50 turns on an air wound core how many turns would that be on a ferrite core? The answer would escape many KW hybrid owners new and old alike.

I once read on QRZ a fellow like you telling people it was easy to wind plate chokes for 1KW linears. He had been doing it his way for years. Just wind a bunch of turns and if it burns up wind another. Not to worry about the fireworks. He posted this after a new member was asking how to determine the parallel resonance and series resonance holes and what test gear would he need. He had a GDO but was having trouble finding the series resonant holes. He did not understand he needed to place short jumper across the choke windings and why he needed to do that. The old timer obviously had no clue as well. Your advice reminds me of that old timer. Just throw a few turns on it.

Your problem is you apparently cant or do not read and you cant get past the fact that people enter the hobby in very different way today than they did 60 years ago. They were

not winding coils since age 9. Through no fault of their own they enter under todays process and it is very easy to see why they would buy a KW hybrid as their first rig....reputation, economics, and availability.

I dont know why you got fixated on wave traps and overlooked ant step up xfmr L8. Maybe pining for those days when you were 9 years old? It doesnt matter.

I will waste the key strokes one last time:

I DID NOT TELL ANYONE TO JUNK A HYBRID. THE OP DID NOT SAY HE WAS GOING TO JUNK A HYBRID.

IT IS FAR SIMPLER FOR THE AVERAGE KW HYBRID OWNER TO INSTALL A COIL PACK L8 OR L24 OR L25 FROM A PULLED BOARD THAN TO ATTEMPT TO REWIND THEM. AFTER YOU REWIND YOUR FIRST L8 OR L41 YOU WILL UNDERSTAND.

YES REWINDING CAN BE DONE IF NO ORIGINALS CAN BE HAD.

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

A couple of month ago I received a TS520 for FREE.. nice of cousre.
The endtubes were a 6146A an a 6146B. So I swapped them with 2 6146B's from my old TS520SE.
here it comes.

1. I cannot neutralize thePA. I have connected a VTVM AND a rf probe to the set and followed the manual precisely.. But I have turned the TC1 neutralize cap 260 degrees. but no change in deflection of the connected meters... The set is working FB however. But the deip in Ip is not coniciding with the max RF output. .

2. The set is quite deaf on 1.8 en 3.5 Mhz just a loud hiss... when i use a crystal oscillator in the vicinity I do hear the freq of the xtal though.... but a HAM nearby I cannot hear on 80 meters.... Is that just a matter of re-alignment ?? the rest of the band are receiving FB.
I have attached a end fed halve wave for 20 mtrs. so I can only tx on 20 and 10 meter

Tks

At a guess, you'd alter the value of some resistor around the RIT control that feeds the RIT voltage in. I don't have a 530 manual around but on the 520 it appears to come from the FIX CH board - the diagram I have isn't very clear - and consists of a 5k pot and a voltage divider.

I can't help but think that an 8kHz spread on the RIT would be awfully twitchy though.

I might be a typical new ham. I am 61 and have been licensed for about 5 years. I was trained to be a "shop" teacher and had a good background in electronics up to 1976. I also have generally good "hands on" skills for most things.

My first radio was a KW Hybrid. I had problems with it. I followed this forum closely and found that I could do some of the easier tasks like changing power supply caps, finals cage rebuild, alignment (W/O a scope) and mechanical repair. I read everything I could get my hands on and realized that I was over my head in terms of diagnosis and repair of this radio. My electronics training was really related to design and understanding and not repair. I sent my radio out to experts and can now enjoy it with no fear of making it worse than it was when I started it.

I am now restoring some Tube type Heathkits and have found that they have been a great learning tool and I do not worry about screwing them up and find diagnosis and repair to be within my capability. With every step I am learning more and more and perhaps. It also gives me a great deal of satisfaction.

I can relate to those in more isolated or smaller countries as far as being resourceful goes. I am also licensed in Vietnam (there are less than 30 of us and only 10 or less are active), but have found that they are very resourceful when it comes to equipment and repair. Much more so than I am or probably ever will be. Equipment is hard to come by as are qualified repairmen and it is very expensive to repair. It can also be a big hassle to get transceivers into the country. (You can count of being "jacked up" by customs until you show a license and agree on the proper bribe for them to do their job) It makes a lot of sense for them to repair.

In short I am no expert in repairing radio at all, but the people in the hobby have really helped me to learn which is what I think it is all about.
Best,
Kevin

The WWV is part of the band switch on the 520S. I did give that a good cleaning and checked contacts. I suspect as Terry pointed out this is only due to WWV having a different RF amp/mixer section in my case. I plan on getting with a ham this weekend or next who has a sig generator and hopefully getting the bottom of this. Hopefully something simple on the RF board.

Best,

73
Jim, N7JS

Subject: [TS-520_820_530_830] RE: RE: TS-520S Low Sensitivity On All Bands

Hi Terry,

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Terry K9TW.

45976. Ebay Shipping Tips WAS: TS-520S Low Sensitivity On All Bands

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-19 21:21:51 UTC
From: Chris Maness
Topic: 45976 Message: 45976

It sucks when folks don't pack a rig well and/or the carrier drops a rig on the ground. I had that happen to a FT-107M. The seller was such a tight wad he did not spend an extra $4 to insure the package. He also skimped on the packing, so was bent on the heat sync. The thing didn't even transmit for longer than three seconds before the finals popped. He refused to make any concession so ebay forced a refund. His refund bounced, but ebay covered it. I still ended up getting screwed because UPS paid him $100, so he got the rig and got to keep his $375+$100. I on the other hand, had to pay $120 for professional packing (the way it should be done), and shipping. What a nightmare. I would suggest everyone here require there sellers to insure for the value plus return shipping, and require their seller to double box with a 4"-6" gap filled with packing peanuts. The 6" would be for radios over 10lbs like our hybrids. Then absorb the extra shipping cost. You pay more, but save yourself the hassle. Tell the seller if it is not packed well, you will give them a negative feedback.

Good Luck,
Chris Maness KQ6UP

Jim:

Bob might have a point. We do know that the WWV amp and mixer are being powered by the bandswitch but we dont know if the signal path switching diodes are being completely turned off when going to the other band positions.

It wont hurt to measure the voltage at the JAS wire wrap terminal post on the IF board. Should see -6vdc there when in other band positions.

This -6vdc voltage is used to back bias switching diode that shunts the off air signals to the WWV amp and Mixer.

If that bias isnt there then diode may not be turned fully off in the other bandswitch positions shunting some of the off air signal from the normal receive path.

If the -6vdc isnt there go to AVR board and see if it is there. It is produced by a transistor dc to dc converter. Seldom fails but it could

Here's what I am getting: On all the bands (except 3.5 where I get 1 S unit) I'm getting no S-meter indications...just hearing the marker every 25khz. In fact on 21 and 28...the marker is barely audible when peaked. The marker signal sounds very sick...not a steady tone but more like a gurgling tone (that could be a whole different issue however with the marker board). I will try uplugging and re-plugging the relays....on inspection they are firmly in place. Any other ideas are appreciated.

Jim:

With the Marker on and the Drive control peaked and RF gain full CW what S-meter indications do you get on each band?

Marker signal does not pass thru TR relay contacts but suggest you un-plug and re-plug the Aux relay and the Ant TR relay as both may have been jostled around in their respective sockets.

Terry K9TW.

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.
The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.
As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

Jim,
Never heard of this cleaner before now.

I looked it up on the Web. It indicates this is a
Corrosion Inhibitor and Penetrant Lubricant. I
would be concerned as the lubricant can cause the
phenolic wafers to break down. It does not indicate that it's a cleaner.

My suggestion is to get you some DeOxit D5 as it
seems to be the standard that's used by most
people trying to refurbish their radio's. It does
do a good job in cleaning switch contacts.

You can pick it up at most electronic shops or
just go to Amazon and receive it in 2-3 days.

Jim:

Bob might have a point. We do know that the WWV amp and mixer are being powered by the bandswitch but we dont know if the signal path switching diodes are being completely turned off when going to the other band positions.

It wont hurt to measure the voltage at the JAS wire wrap terminal post on the IF board. Should see -6vdc there when in other band positions.

This -6vdc voltage is used to back bias switching diode that shunts the off air signals to the WWV amp and Mixer.

If that bias isnt there then diode may not be turned fully off in the other bandswitch positions shunting some of the off air signal from the normal receive path.

If the -6vdc isnt there go to AVR board and see if it is there. It is produced by a transistor dc to dc converter. Seldom fails but it could

Terry. K9TW.

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Hi Mark,
I've heard of DeOxit as well. The CorrosionX was a product that had good reviews from an online hybrid parts seller. I'll get some DeOxit to have on hand from Amazon. You can't go wrong having it. I've also got a can of CRC QD Contact Cleaner...don't know if you have heard of it. Big can I've had sitting around for at least a decade or so. I like it for the fact it is quick drying, no residue, plastic safe...but doesn't seem to last but a year or two whereas the CorrosionX is supposed to be working a decade or more. We'll probably open up a whole discussion on this stuff...hihi.

Jim,
Never heard of this cleaner before now.

I looked it up on the Web. It indicates this is a Corrosion Inhibitor and Penetrant Lubricant. I would be concerned as the lubricant can cause the phenolic wafers to break down. It does not indicate that it's a cleaner.

My suggestion is to get you some DeOxit D5 as it seems to be the standard that's used by most people trying to refurbish their radio's. It does do a good job in cleaning switch contacts.

You can pick it up at most electronic shops or just go to Amazon and receive it in 2-3 days.

OK that is good. So now need to do some signal injection.

Hopefully not a bad L1 Ant Step Up transformer. Start by injecting 14.2 mhz at ANT at around 50uv or -73dBm. That level should give you apporx S9 indication.

If the Sig Gen doesnt have calibrated output inject a low level and slowly bring up until you see some S meter indication.

If receive is low injecting at ANT (primary of L1) then move to RFG which is secondary of L1. If normal receive at RFG you know that L1 is bad. Check with Bob Mansker to see if he has a RF board. It would be good to have a spare if you plan on keeping the radio. Even a board that you could harvest from would be good to have. If still low injecting at RFG then inject at TP-1 or MD. Just follow the signal path on the schematic. If low at L1 and Q2 then your radio may have been victim of nearby lightning (ESD) or accidental TX. Usually receive will be dead or very weak from either event.

Remember if you get to the Drain of Q2 you are now no longer looking at your 14.2 mhz signal. It will have been mixed with Het Osc to produce the 8.830mhz RIF signal so at this point have to change sig gen frequency to 8.830mhz. You already know that the IF amp chain is good as you get good WWV signal so problem has to be on RF board. So if no good at MD or TP-1 you need to take DC voltages at Q2 (DSGG).

There is one other thing you can check and that is Het Osc signal level. You can check the level at TP-3 with RF probe and VTVM or DMM. Should be close to 1.0 rms RF volts on all bands except WWV which has its own Het Osc. .

I would use a .01 blocking/coupling cap in the RF sig gen hot lead. Value is not critical. Just dont want any vdc back to your sig gen.

That is enough to keep you busy. .

Dave,

Try switching the SG switch on and off a couple of times, also try rotating the carrier pot through it's range as it could have a build up of crap on the wipers. Report back and we can then start to trouble shot. Start with the basics and we can always go really technical.

Dave VK5PDL,

If the SG switch were the source of the problem, he would not be able to adjust the bias pot to achieve 60ma of idling current in the final tubes.

If he suspects the tubes are at fault then he can simply swap them for know good tubes.

The question I have is his statement that says;

"so far everything checks out but I'm NOT getting any out put power.."

What are you saying? If you are not seeing any output on your watt meter, then how can "everything check out"?

If he believes the tubes are the source of your problem, I wonder if he has tried substituting the suspected bad tubes with known good tubes?

Mike,

I disagree Mike. How can the SG Switch, if it's bad, be the source of
his loss of RF output when he clearly stated in his post that he was
able to adjust the bias pot for 60ma of idling current in the final tubes?

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.
The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication

when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.
As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at 28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

46001. TS-180S Transverter Use

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-21 16:02:08 UTC
From: Byron Tatum
Topic: 46001 Message: 46001

Hello-

Sorry for the off-topic post but I thought someone here would know.

I picked up a fairly nice TS-180S and am considering using it as an IF for my transverters. I have studied the operating and service manuals but cannot find any specifics regarding the use of the transverter connector. I have used a TS-830S as an IF for my transverters in the past, and I have the proper DIN connector for doing such.

My questions are:

1. Will the transverter DIN cable for my TS-830S work for the TS-180S DIN socket (pin-out and function)?

2. Are the low-level transverter transmit output levels of each radio similar?

3. I recall that when using transverter with TS-830S I turned the Screen Grid switch off, however is there anything I need to do to the TS-180S in this regard?

Thanks everyone for the time and help.

Ok Terry,
All understood.
Will check it tomorrow.... but what I still don't understand is, that the rig is working FB on 7 mhz and higher,
So it must have drive on pin 5 otherwise it wouldn't work at all.... right?

but will check it and let you know the outcome..

Many thanks for spending your time to answer me... very much appreciated

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at 28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

This is a question for anyone who may have used one of these.
I obtained a Heath Kit SB-620 Scanalyzer. What I need to know is if anyone has used this item on a Kenwood TS-830S? I have to clean it up and free up some controls as it has set in storage for a log time. The last time it was use was on a HW-101 transceiver.
The ham I got it from said he has some other coils for it. If memory serves me the HW-101 used close to the IF frequency's that the TS-830S uses. I could be wrong on that as it has been 20 years since I built and used my HW-101. I gave it away 12 years ago. Any ideas out there?????

Dave,

You will NOT get any "movement of your needles" is SSB unless you either speak into the microphone(if any) or inject a tone in to the radio via the microphone connection or a couple of other places. Even then ,if it is a modulated signal, you will not show "full output" as the "meters" you seem to have available will not read correctly an SSB output signal. With out going into much detail here, I will suggest you go to Ken Kenski's web site: k4eaa.com and look for how to figure out if your "driver tube" or "finals" or, some other components may be at fault for your low output. Possibly a "basic alignment" outlined in the "operators manual" is a good place to start.

Adenum:

IF you have a mic..your rig is properly "tuned up" for operation...meter switch to ALC....key(put into send) your rig..speak into the mic...and advance the "mic" control until the needle just flicks off the resting position...you can also put the meter into "RF" after this and check for RF output.
NOTE: you will not see anymore than about 20-30 watts indicated on the meter> This is normal

Topic: 46003 Message: 46008

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

This is a question for anyone who may have used one of these.
I obtained a Heath Kit SB-620 Scanalyzer. What I need to know is if anyone has used this item on a Kenwood TS-830S? I have to clean it up and free up some controls as it has set in storage for a log time. The last time it was use was on a HW-101 transceiver.
The ham I got it from said he has some other coils for it. If memory serves me the HW-101 used close to the IF frequency's that the TS-830S uses. I could be wrong on that as it has been 20 years since I built and used my HW-101. I gave it away 12 years ago. Any ideas out there?????

The SB-620 came with coils for 3395 and 455. You will have to find out which you have.

For any other IF frequency you will have to make your own coils if you know how.

Subject: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

THANKS JOE......WILL LOOK INTO IT

---In TS-520_820_530_830@yahoogroups.com, <stilesjoseph@...> wrote:

Dave,

You will NOT get any "movement of your needles" is SSB unless you either speak into the microphone(if any) or inject a tone in to the radio via the microphone connection or a couple of other places. Even then ,if it is a modulated signal, you will not show "full output" as the "meters" you seem to have available will not read correctly an SSB output signal. With out going into much detail here, I will suggest you go to Ken Kenski's web site: k4eaa.com and look for how to figure out if your "driver tube" or "finals" or, some other components may be at fault for your low output. Possibly a "basic alignment" outlined in the "operators manual" is a good place to start.

Wally:

Yes for any band that you are getting RF output power as seen on RF position of the panel meter or on an external wattmeter then you have to have RF drive at the control grids of your 6146 finals. If you have RF drive then you have to have feed thru power from the control grids to the plate circuit thru that 0.22pf Cgp.

If you try neutralizing on 40 meters will see feed thru power, but will be lower than what I gave you for 10 meters. Probably a high of approx 270mv and low of approx 20mv. If using a single germanium diode probe then might just see slight meter indication as the diode barrier will be approx 250mv.

What kind of RF probe are you using?

Terry

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Ok Terry,
All understood.
Will check it tomorrow.... but what I still don't understand is, that the rig is working FB on 7 mhz and higher,
So it must have drive on pin 5 otherwise it wouldn't work at all.... right?

but will check it and let you know the outcome..

Many thanks for spending your time to answer me... very much appreciated

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at 28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.
The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.
As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

A couple of month ago I received a TS520 for FREE.. nice of cousre.
The endtubes were a 6146A an a 6146B. So I swapped them with 2 6146B's from my old TS520SE. here it comes.

1. I cannot neutralize thePA. I have connected a VTVM AND a rf probe to the set and followed the manual precisely.. But I have turned the TC1 neutralize cap 260 degrees. but no change in deflection of the connected meters... The set is working FB however. But the deip in Ip is not coniciding with the max RF output. .

2. The set is quite deaf on 1.8 en 3.5 Mhz just a loud hiss... when i use a crystal oscillator in the vicinity I do hear the freq of the xtal though.... but a HAM nearby I cannot hear on 80 meters.... Is that just a matter of re-alignment ?? the rest of the band are receiving FB.
I have attached a end fed halve wave for 20 mtrs. so I can only tx on 20 and 10 meter

Tks

Dave,

Do you have the TS-530 operator's manual and if so have you taken the time to thoroughly read and understand the information presented in the TS-530's operator's manual before you attempted to operate your TS-530? Quite often people fail to perform this simple but necessary step and end up experiencing problems similar to what you have described.

Also, based on your statement about your level of electronic knowledge,

"When it comes to electronics you might as well be speaking zulu to me..."

I'm sorry to say Dave but you do not have the necessary skills and knowledge to properly and "safely" service/repair your TS-530. Therefore, if your TS-530 requires any service/repair to fix any problems it may have, I highly recommend you find a local ham or person who has the experience, knowledge, and skills to assist you in servicing your TS-530. There are voltages inside the TS-530 that can easily kill you.

Subject: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

Bill,

I have the earlier version of the SB-620, the HO-13. There isn't that much difference between the SB-620 and the HO-13, some circuit improvements in the SB-620 and a new cabinet but basically they are the same "Scanalyzer" producing very similar spectrum displays.

I can tell you from experience using the HO-13, it's not going to give you the display you may be looking for that a dedicated Spectrum Analyzer will give you. The HO-13 and the SB-620 lack the sophistication that a dedicated Spectrum Analyzer is designed to produce. I could be wrong but I think you may be disappointed by the SB-620s spectrum display.

Mike, Bill: I also want to achieve the same objective with my '830, but with a totally different methodology:

I have been looking at those inexpensive SDR (software defined radios) that can be had for about $25 or so plus a frequency converter made for the SDR for about $50. The combo allows coverage to BOTH IF frequencies in the 830, and the available software appears to offer a whole host of applications.

It seems to me that it should be practical with this setup to get all or most of the features of the 620 (or more). Right now all I have done is some research, but if anyone else in the group has experience along these lines, I would surely like to hear it.

For the record, I've been licensed for over 50 years, still own many tube rigs, tube testers, and sever thousand new, boxed, tubes... and a lot of experience repairing, modifying, etc. Always been too clumsy to wind coils with #40 wire..LOL

I agree with Mike.

Nice to have the Heath units to complete your Heath station layout, but compared to todays technology more of a novelty item. You could never give any off air reports to anyone. The resolution just isnt there.

Suggest you take a look at the modern SDR units like the L-pan and recommended sound cards for your lap top.

Take a look at Jan N8CBX QRZ page. He is a member of this forum if you want to contact him and discuss SDR panadapters married to KW hybrids 8.830 IF.

Of course you get what you pay for so wont be cheap and wont get one for price of old Heath monitor!

Terry K9TW.

Joe was not stating you can't solicit help with your 820. I think you
may have misunderstood what Joe is saying. Quite often threads tend to
become more of a "chit chat" about issues that are not part of the
original problem. Those types of discussions tend to get out of hand and
that appears to be what Joe is saying.

To use a SB-620 or HO-13 with a receiver requires tapping into the one of the mixers.

There is a program called "Spectran". It works on the audio and gives a spectrum of what is in your audio bandpass.

The problem comes from the narrow filters in typical SSB receivers.

If one were to make an adapter that taps into the IF somewhere ahead of the filter with a wider bandpass you could get your spectrum display.

http://www.sdradio.eu/weaksignals/spectran.html

Subject: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

I believe we all did a similar discussion back a year or so ago.
These old spectrum displays are more eye candy then useful instruments unlike some of the spectrum displays you see with today's rigs. I married a SB-620 to my Kenwood Twins some years ago. Even with the proper IF front end in the SB-620, I still have to build a voltage amplifier to bring the pickup signal high enough so that I could see a decent display on the screen. In the end, it was no more useful then using a SM-220 and BS-# adapter. I find that main use for the SB-620 is just a pretty eye candy accessory for other Heathkit SB-type transceivers. The SDR approach is a much better avenue to pursue with a display result that can provide some good and accurate viewing and useful data.

I have the earlier version of the SB-620, the HO-13. There isn't that much difference between the SB-620 and the HO-13, some circuit improvements in the SB-620 and a new cabinet but basically they are the same "Scanalyzer" producing very similar spectrum displays.

I can tell you from experience using the HO-13, it's not going to give you the display you may be looking for that a dedicated Spectrum Analyzer will give you. The HO-13 and the SB-620 lack the sophistication that a dedicated Spectrum Analyzer is designed to produce. I could be wrong but I think you may be disappointed by the SB-620s spectrum display.

Subject: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

To add to what Pete has said.

The SB-620 and Kenwood BS-# were designed to connect to the low IF in the receivers. Their bandwidth is limited by the bandwidth at the point of connection.

The better place to connect is at the output of the 1st mixer.

Using a SDR with a computer gives you a better display than you get from a 3" CRT

I believe we all did a similar discussion back a year or so ago.

These old spectrum displays are more eye candy then useful instruments unlike some of the spectrum displays you see with today's rigs. I married a SB-620 to my Kenwood Twins some years ago. Even with the proper IF front end in the SB-620, I still have to build a voltage amplifier to bring the pickup signal high enough so that I could see a decent display on the screen. In the end, it was no more useful then using a SM-220 and BS-# adapter. I find that main use for the SB-620 is just a pretty eye candy accessory for other Heathkit SB-type transceivers. The SDR approach is a much better avenue to pursue with a display result that can provide some good and accurate viewing and useful data.

Actually Bob, what I said was to connect the panadapter/spectrum analyzer to the input of the 1st IF which is the output of the 1st mixer. In the case of the TS-830S which has a double conversion receiver with 1st IF stage/mixer 8830 KHz and 2nd IF stage/mixer 455 KHz, you don't want to connect the equipment to the "low IF of the receiver". The seeable spectrum on the screen will be greatly diluted by the actions of the 1st IF amplifier if you connect it to the lower IF/mixer.

Pete,

That's the point I was trying to make.

It also needs to be LOOSELY coupled to avoid de tuning the 1st IF transformer.

In the case of a Kenwood hybrid I would install an emitter follower near the 1st mixer as a buffer then in my case I would use RG-174 to get the signal to the rear panel.

I assume a SoftRock 40 would be just fine for this application.

Dave,

Do you have the TS-530 operator's manual and if so have you taken the time to thoroughly read and understand the information presented in the TS-530's operator's manual before you attempted to operate your TS-530? Quite often people fail to perform this simple but necessary step and end up experiencing problems similar to what you have described.

Also, based on your statement about your level of electronic knowledge,

"When it comes to electronics you might as well be speaking zulu to me..."

I'm sorry to say Dave but you do not have the necessary skills and knowledge to properly and "safely" service/repair your TS-530. Therefore, if your TS-530 requires any service/repair to fix any problems it may have, I highly recommend you find a local ham or person who has the experience, knowledge, and skills to assist you in servicing your TS-530. There are voltages inside the TS-530 that can easily kill you.

Dave,

Do you have the TS-530 operator's manual and if so have you taken
the time to thoroughly read and understand the information
presented in the TS-530's operator's manual before you attempted
to operate your TS-530? Quite often people fail to perform this
simple but necessary step and end up experiencing problems similar
to what you have described.

Also, based on your statement about your level of electronic
knowledge,

"When it comes to electronics you might as well be speaking zulu
to me..."

I'm sorry to say Dave but you do not have the necessary skills and
knowledge to properly and "safely" service/repair your TS-530.
Therefore, if your TS-530 requires any service/repair to fix any
problems it may have, I highly recommend you find a local ham or
person who has the experience, knowledge, and skills to assist you
in servicing your TS-530. There are voltages inside the TS-530
that can easily kill you.

---In TS-520_820_530_830@yahoogroups.com, <macklinbob@...> wrote:

☐ Pete,

That's the point I was trying to make.

It also needs to be LOOSELY coupled to avoid de tuning the 1st IF transformer.

In the case of a Kenwood hybrid I would install an emitter follower near the 1st mixer as a buffer then in my case I would use RG-174 to get the signal to the rear panel.

I assume a SoftRock 40 would be just fine for this application.

Subject: RE: Re: Re: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

Actually Bob, what I said was to connect the panadapter/spectrum analyzer to the input of the 1st IF which is the output of the 1st mixer. In the case of the TS-830S which has a double conversion receiver with 1st IF stage/mixer 8830 KHz and 2nd IF stage/mixer 455 KHz, you don't want to connect the equipment to the "low IF of the receiver". The seeable spectrum on the screen will be greatly diluted by the actions of the 1st IF amplifier if you connect it to the lower IF/mixer.
Pete, wa2cwa

---In TS-520_820_530_830@yahoogroups.com, <macklinbob@...> wrote:

☐ To add to what Pete has said.

The SB-620 and Kenwood BS-# were designed to connect to the low IF in the receivers. Their bandwidth is limited by the bandwidth at the point of connection.

The better place to connect is at the output of the 1st mixer.

Using a SDR with a computer gives you a better display than you get from a 3" CRT

I believe we all did a similar discussion back a year or so ago.
These old spectrum displays are more eye candy then useful instruments unlike some of the spectrum displays you see with today's rigs. I married a SB-620 to my Kenwood Twins some years ago. Even with the proper IF front end in the SB-620, I still have to build a voltage amplifier to bring the pickup signal high enough so that I could see a decent display on the screen. In the end, it was no more useful then using a SM-220 and BS-# adapter. I find that main use for the SB-620 is just a pretty eye candy accessory for other Heathkit SB-type transceivers. The SDR approach is a much better avenue to pursue with a display result that can provide some good and accurate viewing and useful data.

---In TS-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

Bill,

I have the earlier version of the SB-620, the HO-13. There isn't that much difference between the SB-620 and the HO-13, some circuit improvements in the SB-620 and a new cabinet but basically they are the same "Scanalyzer" producing very similar spectrum displays.

I can tell you from experience using the HO-13, it's not going to give you the display you may be looking for that a dedicated Spectrum Analyzer will give you. The HO-13 and the SB-620 lack the sophistication that a dedicated Spectrum Analyzer is designed to produce. I could be wrong but I think you may be disappointed by the SB-620s spectrum display.

Subject: [TS-520_820_530_830] RE: Heath Kit SB-620 hook up to Kenwood TS-830S

The SB-620 panadapter/spectrum analyzer, as is, has only enough gain to take it 3400 or 3500 KHz and probably not much higher. Modifying it to work with a 3395 KHz IF (TS-520 or similar) can be done. It's in the SB-620 manual. But the panadapter is only effective when connected to the input to the 1st IF. The TS-830S 1st IF is 8830 KHz. You would have to a add a mixer to the SB-620 to bring the 8830 KHz signal down to something the SB-620 can use. In the end, it probably is not worth the time, effort, and expense.

This is a question for anyone who may have used one of these.
I obtained a Heath Kit SB-620 Scanalyzer. What I need to know is if anyone has used this item on a Kenwood TS-830S? I have to clean it up and free up some controls as it has set in storage for a log time. The last time it was use was on a HW-101 transceiver.
The ham I got it from said he has some other coils for it. If memory serves me the HW-101 used close to the IF frequency's that the TS-830S uses. I could be wrong on that as it has been 20 years since I built and used my HW-101. I gave it away 12 years ago. Any ideas out there?????

46032. TS-820S Final Cage Repair

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-23 20:54:49 UTC
From: kk6ezq
Topic: 46032 Message: 46032

Dear Group,

My rig was arcing in the final cage area when I tuned to frequencies higher than the 40 meter band. It seemed to be coming from the wafer switches in the final cage. I disassembled the final cage enough that I can access the wafer switches for inspection. There has been extensive arcing and carbon trails, some of the phenolic is missing.

I am not sure what my options are for repair going forward. I love the radio, its great sound quality, and the fact it is my first HF tranceiver. I have invested time in replacing all tubes, new final caps, drive resistors and brass bandswitch couplers.

I am sure those of you with experience with these parts appreciates the workmanship and alignment challenges that the assemblers had. Any suggestions on what to do about replacing the wafers, or other options would be appreciated.

Yioutta

The HEATER switch has nothing to do with the loss of the ALC/IP/HV/RF meter switch functions. All of the meter switch settings are "disabled" in receive and are only "enabled" when the 820 switches to transmit (relays energize). As long as the relays do not energize when attempting to switch the 820 from receive to transmit, the meter will not display any of the meter switch setting values.

Yioutta, if "Yioutta" is not your name and since you did not indicate you have a call sign when you applied for membership to the group, please include your "name" at the end of all your future messages/responses/posts. Your first name is fine. "Yioutta_99" is not an acceptable identification/name for you in this group. Yioutta_99 can only be used as part of your email address.

Steve,

I do not want to be a "buzz kill" but, if the switch wafers in the final cage area have suffered
significant damage...ie., "missing phenolic," carbon arcs & trails," it most likely beyond possible repair without replacing the entire assembly. I have recently seen some "final cages" for sale on "ebay"...also Bob Mansker.... ke5ftf "at" mail dot com may have what you need...email him.

   If it comes down to it...you now have a top notch receiver.

   Sorry.............

The IF output on the back of the TS930 is not there for a BS-8 panadapter connection. That IF output is after the IF amplifiers and is used to view the audio spectrum of the signals. That IF output of the TS-930 is designed to connect to the front panel vertical input of the SM-220. Page 28 of the TS-930 operating manual. states that the SM-220 cannot be used as a band scope. Panadapters are connected after the 1st mixer and before the 1st IF. The 1st mixer/1st IF of the TS-930 is roughly 44 MHz. The BS-8 was designed for a 8.83 MHz input. The 2nd conversion stage of the TS-930 is 8.83 MHz and you can try to make a connection there but I'm not sure how accurate it would be then as a band scope. Worse case, it just makes pretty eye candy when you're receiving.

46040. Very low sensitivity on WWV

My TS520SE is aligned nicely on all the amateur bands, showing around S8 on the internal calibrator signal.

Even when conditions allow, I can't hear any WWV time signal! If I turn on marker signal for that position on bandswitch I can hear the marker (much quieter than on other bands) but the S-meter doesn't shift!

Today I put on bench to investigate, using proper signal generator. With a 300uV input on 15.000 MHz I saw S4.5 on meter, having peaked T4/T5 then T3 on the RF board.

If I put same strength signal in at 14MHz I see S9+10dB! I'm losing a lot of gain somewhere on WWV.

Looking at circuit/block diagram Q4 on RF board is WWV RF amp. I suppose this is a suspect but problem is it's soldered into board, whereas some other transistors are in convenient sockets. It looks like a nightmare to remove RF board given the drive variable capacitors are attached to it and the plate and load shafts run above it. Also many wire wrap connections to board which I'm reluctant to risk stressing by moving the board.

Please can anyone help with suggestions for troubleshooting the WWV problem, and also with any guidance on removing the RF board if that becomes necessary? Though to be honest I would happily live without WWV rather than risk damaging connections to RF board, but it's just that everything else on the 520SE is working beautifully so would be nice to restore to complete working condition.

Thanks for advice.

Adrian G4IQW

Go to JAS terminal and measure the votage there and make sure you have 14vdc in WWV position. Should be -6vdc on other bands. This voltage is used to bias on and off switching diodes to switch the signal path from Ant input.

Also make sure you have 14vdc at J14 terminal as it supplies the Drain and Collector voltages for the WWV Amp, Mixer, and Het Osc.

If voltages missing or low try cleaning bandswitch decks S5-6 and S5-7.

I should have a 820 final PA switch in good condition, sell them for $22.00 plus $3.00 to mail in USA...
Also the complete PA cage unit with the Switch & Final Choke for $50.00 plus $12.00 to mail Flat Rate...
I cut the grounding lugs on the bottom of PA so you can slide the old out & new one in with not much effort...
You can PM me off the group at ... keFIVEftf "at" mail.com
Bob

---In TS-520_820_530_830@yahoogroups.com, <kk6ezq@...> wrote:

Dear Group,

My rig was arcing in the final cage area when I tuned to frequencies higher than the 40 meter band. It seemed to be coming from the wafer switches in the final cage. I disassembled the final cage enough that I can access the wafer switches for inspection. There has been extensive arcing and carbon trails, some of the phenolic is missing.

I am not sure what my options are for repair going forward. I love the radio, its great sound quality, and the fact it is my first HF tranceiver. I have invested time in replacing all tubes, new final caps, drive resistors and brass bandswitch couplers.

I am sure those of you with experience with these parts appreciates the workmanship and alignment challenges that the assemblers had. Any suggestions on what to do about replacing the wafers, or other options would be appreciated.

Thanks very much Terry the voltages do check out low. In WWV position voltage at JAS and J14 measured +12.3V but then dropped after a couple of minutes to 11.7V At JAS all other bands stable supply -5.9V Will try cleaning those wafers as I'm sure I had WWV copying time sigs in the past. 73 Adrian G4IQW

Have just tried cleaning switch decks with shots of Servisol Super 10 (I'm assuming decks S5-6 and S5-7 live at end of shaft under metal cover?) Still getting low volts JAS. was 12.3V initially but now reading 11.9 after declining slowly for about 2 mins after powering up. Does the decline from initial value give any clue to problem? On other bands it's steady -5.95V

Adrian

I dont have a TS520S or SE here at the moment to take any vdc measurements so can only go by values noted on schematic. I would think that if you have approx 12vdc on J14 and JAS with band switch at 15mhz then should have good WWV copy.

Curious what is the 14vdc level at the AVR board? If you have good 14vdc there then jumper it to J14 wire wrap terminal post and see if gain comes up.

In my experience seldom have failures of active devices. It can happen but I would not reach for replacing mosfets or transistors at this point. .

Good plan thanks Terry. I will see what is voltage at AVR and patch it to JAS if necessary to test. Clearly all is fine with rest of IF amp fed by band signals or WWV, so if there is a problem I can only think it's with the WWV rf amp ior the WWV mixer. But my experience like yours that active devices rarely fail unless talking final stages or psu regulators. Will keep investigating and thanks very much for your help. 73 Adrian G4IQW

Go see what you have for input and output voltages at the 14vdc Pi filter (C-L-C).

At input C22 would expect it to be in excess of 15vdc and perhaps around 14.5vdc at the output C21. Could have tired filter caps.

However you report normal receiver performance on all bands other than WWV.

What do you have at AVR board for regulated 9vdc level?

Terry K9TW

Topic: 46049 Message: 46049

Jimmy, WB2KNR ran the Saturday net. He had 25 check-in with poorband conditions. There were 2 new check ins, KD8PFN, and W8NIC. We had the following number of radios checking in.

6 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
4 running TS-830S

Jimmy was running my TS-520.

The Sunday□s 20 meter net had 16 stations checking in under good band conditions. We had 6 stations checking in from California. There were 5 new stations checking in, N6PMG, AE2U/6, W6WTJ, K6PPP, and N6VIA.

Out of those, there was:

2 running TS-520(x)
0 running TS-530(x)
1 running TS-820(x)
2 running TS-830S

The rest were running non hybrid equipment. I was running my TS-820s/R820.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20

I have a TS830S and was reading different tuning procedures. I think I'm good with tuning up okay but found this statement for checking the 12BY7A. I don't understand what is meant by "the driver tuning control" (what's this??) as compared to " the drive level control (potentiometer)" <---((this one I'm okay with)).
Any light you could shed would be greatly appreciated.

When in TUNE, you peak the driver tuning control (which is grid tuning on xmit, and receiver preselect peaking on receive) for a peak in ALC reading, and then you can adjust the drive up and down with the drive level control (potentiometer), which only works on TUNE and CW and does nothing in the SSB mode. When in TUNE and after the driver stage tuning is peaked, see if you can turn the drive level control up so high that the ALC meter "pegs" (goes offscale to the right). If so, the 12BY7 is probably okay.
Thanks, Jerry K4GEW

The "Driver tuning control" is the same as the "DRIVE" control in the upper right corner of the front panel.

The "drive level control" you are referring to is the "CAR" control.

After completing peaking the ALC meter indication in TUNE mode with the DRIVE control, wait a few extra seconds before unkeying the transmitter. Watch the ALC meter and if the ALC meter indication starts to fall back towards zero, that indicates a weak driver tube. This is assuming there are no other problems with your KW hybrid.

The above simple driver tube test should be conducted after the KW hybrid has warmed up for 10 minutes and the test should be conducted on 10 meters which is the band a weak driver tube will show up quicker than on the lower bands. Also, I recommend the test be conducted with a 50 ohm dummy load connected to the KW hybrid. I recommend all hams tune their transmitters into a 50 ohm dummy load before switching to their antenna. If you don't have a 50 ohm dummy load, I highly recommend you buy one. MFJ sells a couple of 50 ohm dry dummy load:

MFJ-260C - $39.95 - 300 watts
MFJ-264 - $74.95 - 1.5KW

What ever dummy load you purchase or use, ensure you adhere to all the maximum ratings. Failure to do this can result in damaging your dummy load.

I am getting the 811H amplifier shortly and I am looking to use it with my 520. This is going to be my first amplifier. Looking at the manual it appears I can hook this amplifier directly to the radio using the remote plug on the rear of the rig using pins 3 or 5 to ground, depending on NC or NO contacts connected to the amplifier with an RCA plug, and a coax jumper. Am I correct in this or am I missing something. Thanks

John,

You can use simple stereo interconnecting cables (RCA plugs on both ends). I divide the cable in half. Each section will have an RCA plug. The RELAY cable's cut end, strip the outer covering exposing the shield and center wire. The amp's RELAY cable's center conductor connects to the 520's REMOTE socket pin 5 (N.O.) and the shield to pin 1 or 4 (ground). The amp's ALC cable center wire connects to the 520's REMOTE socket pin 6 and shield to pin 1 or 4. Other than a short length of coax cable between the 520 and the amp, there's no other connections required.

Also, read the AL-811H operator's manual THOROUGHLY, paying close attention to the discussion concerning setting the LOAD control and GRID current meter indications.

Good afternoon fellow hybrid lovers:

I have a TS-820 that is deaf with the exception of a low amplitude hiss from the speaker. Years ago, in other radios,

I remember that in order to receive, one had to have a microphone connected to complete a electrical path. I don't

have a mic for it yet

Before I dive in any further, I am wondering if this is the case for this radio. Does a microphone need to be connected

to the TS-820 to receive audio from the speaker?

Many thanks in advance for sharing your knowledge.

Tom

Mike, Thank you. It would be nice if everyone could use the names on the front panel.

I do understand most of the folks who have been around these radios awhile understand all the possible terms for things but when someone with a short time with them and the fear of god put into them about damaging the tubes gets 2-3 different terms for the same thing it can become intimidating. I'd like to hope the old timers wouldn't be put off by using the simpler language. It would be greatly appreciated.
Thanks again, Jerry K4GEW

Tom,

The TS-820 does not require a microphone connected to hear receive in
the speaker. Who ever said you have to have a microphone connected to
the TS-820 to hear receive audio, obviously had no clue what they were
talking about. There are some 11 meter transceivers that require a
microphone, a couple I can think of off the top of my head are the
Johnson Messenger I and II as well as the Johnson Messenger 223 series
transceivers. However, you can be assured that none of the KW hybrids,
TS-520, TS-530, TS-820, and TS-830 transceivers do not require a
microphone connected to hear receive audio.

Adrian:

It sounds like you are in the correct place. Only one C-L-C filter that I am aware of.

As I said dont have a 520S here to take measurements for comparison. Voltages seem low to me, but probably not enough to affect your WWV Amp, Het Osc, or Mixer performance.

If had rig here I would apply 14vdc to J14 terminal using my dc bench supply to see if it makes any improvement from 12vdc that you report. Also with 12 vdc applied to JAS the switching diodes should be shunting the RF signal from Ant terminal. Unless have bad D11 or bad D12. Not sure if you can place a jumper from ANT terminal to anode of D11 or not?

Have you tried running transformers T5 and T4 completely thru their ranges to make sure you have them peaked? Also when they are peaked then need to reduce sig gen level and adjust T3 for max on the S-meter.

Thanks for your reply. I recently purchased this from an SK's estate. The radio is new to me.

The S meter shows full deflection. I have tried turning the AGC off without success.

There is a shorting plug in the back and it only appears to have 2 pins connected together.

I will have to do some research to see if that is correct.

I'm am just trying a few things before I remove the covers.

Thanks!

Tom

Tom,

If your rig has the "shorting plug" and has only 2 pins, #'s 8 & 9 "connected together," that is correct.

Look in the "operators manual." It shows you the info you need.

Make sure that the RF GAIN control is turned FULL RIGHT...or full clockwise to start.

Also make sure that the "cal" function is not turned on.

Since you do not know the whole history of this rig...the "golden screwdriver" may have been used.

Suggest you review the "operators manual" and take a look at the "service manual" also. Setting the zero or resting position of the "S" meter is not hard...but the S-9 setting requires
input from a signal generator...but at times can be "fudged" at bit after a basic IF/RF alignment...which is covered in your "operators manual."

I took a peek at the shorting plug and pins 4 and 5 are connected. In addition, another cable came with the rig that has an identical connector to the shorting plug

on one end with 2 cables coming from it. Each cable is terminated on the other end with an RCA (phono) plug. At the RCA end, the cables are labeled ”RELAY T”

on one of them and “ALC B” on the other. At the Amphenol end , the center conductors of the 2 cables are connected to pins 5 and 6 with the shields

connected and tied to pin 4. I’m wondering if this was to connect the rig to a linear amp?

Thanks!

Tom

Tom,

  Ok...no problem. The "remote socket" is indeed used for linear amplifier control. There is no need to have anything plugged into this unless it's being used to operated an amplifier.

I understand you got the rig from a now SK. How long had it sat around without being used? These rigs don't like to sit around and not be used. Various controls, pins, sockets...etc. will
get corrosion and other "junk" on them. Many times, a good cleaning of ALL pins, sockets, controls..etc is a good first step. As others here may attest also...many problems have been
"fixed" by a good cleaning of the above stated items. I use DEOXIT D5...available at Radio Shack.(arrg)...any good electronic supply house, some times it can be found at a good music store...one that sells guitar amp..especially, or mail order....canned air or "air duster" can be found a computer stores, office supply stores...and Walmart.

Have you double checked position of ALL controls...especially the RF gain? That's a common "whooops."

If you do decide to clean all the "stuff"...TAKE NOTES/PICTURES or draw diagram of what plug you removed from where or what...especially the IF board! Use a "sharpie" to label connectors works too.

  Good luck...keep us posted

Hi Terry

Thanks for new ideas to try!

To my shame I don't have variable bench psu. But I did check T4/T5 again adjusting cores through dull range. They were correctly peaked. I had also maxed T3 s-meter reading.

I did manage to get jumper from D11 anode to the antenna input but made no difference, at least on marker signal. I had put away sig gen for now so if the marker is injected at antenna should be same as input at antenna terminal.

I haven't tested D11 or D12 yet. To do so I may have to snip one lead then resolder.

These old tanks are pretty tough, and if the radio is basically healthy and you're tuning up into a dummy load (ie. no reflected power) and only using short bursts of trasmit, it's hard to get it wrong.

I wanted to test the transmit frequency stability of my TS-520 so I ran it into a chunky great 250W Rohde and Schwarz dummy load (looks like an old-fashioned heating radiator, only a little smaller than the 520) for a good ten minutes. At 80W output the output valves were just about warm. I did have my hand on the SEND switch ready to chop the power in the event of any distress, but I needn't have worried. I don't recommend you try this, unless you know everything in the PA cage is utterly beyond reproach.

Just keep your hand on the SEND switch, check your dummy load isn't trying to melt its way to China, and don't do anything silly.

Oh, and the DRIVE control also functions as the RX preselector tuning, so if you tune on receive for the strongest signal (or most noise) you'll be about the right place for peaking the DRIVE control on transmit.

Adrian:

Assuming you are jumpering from Ant to anode of D11 properly with no improvement then it doesnt matter if the diodes are open or not. You should be shunting the 15mhz signal to T5 step-up transformer thru coupling cap C40.

What the jumper test tells you is that the problem is beyond the diode switches.

It is usually not possible to perform forward/reverse diode testing in circuit without lifting either the cathode or anode end of a diode.

If you can access anode of D11 then easy to inject 15mhz there from RF sig gen and see if it works. If not then inject at Drain of Q5 and so on down the signal path. Use a .01uf coupling cap in hot lead of sig gen.

You essentially have two front ends for this receiver.. One for the ham bands and one for 15mhz. Designers have two choices to switch the common antenna input to the two different front ends. One would be with mechanical bandswitch contacts as you suggest and the other would be to employ electronic switching using diodes and then switching the bias voltage to them. Using the diode method is easier and cheaper.

If you look at the original 520 you will see two front ends. Instead of using a common ANT it has two seperate Ant paths that are switched with a seperate switch not on the bandswitch decks. It also uses another switch to bias on diodes to select the output from each front end to feed the 8.830 RIF to the IF chain..

So one way or another you have to switch the off air input signals from one front end to the other and then switch the outputs.

Look at the schematic and will see the Marker output in dashed line that is in parallel with the normal off air input to the RF board. Marker takes exact same path as ham band signal does.

By RF signal injection should find where losing the signal and then take dc voltages at Q5, Q4 and Q8 as need is indicated. Beyond this there is not much more that I can offer.

At this point we need to ask if there is a member with covers off TS-520S who can measure J14 and JAS and see if they have 12vdc and not 14vdc and if WWV receive works well at that lower supply voltage level.

Agree Tanks are pretty hardy as long as dont have long off resonance key down times. Even then they can handle the elevated plate current for some time. Just no reason to stress them needlessly.

Quickest way to have instant 6146 failure is to have thermal run-away from loss of operating bias. Dirty bias pot can cause this when attempting to set 60ma zero signal current. Some people deliberately test the finals by adjusting the bias voltage and run Ip up to 350ma. I do not recommend this. It is a needless static dc test that tells you nothing about how tube works with RF drive.

The Drive control position for Rx and Tx can be out of sync if coil pack alignment is not done correctly. I see this regularly.

There is no reason to stress the 6146 finals when testing the Driver stage. Just simply turn off the SG switch. Now in CW mode with 6146 heaters on you can peak the Drive control and increase the CAR level pot for full scale ALC indication. Leave rig keyed for a few seconds and if you can attain FSD and it does not slowly drift off you know Driver stage is good. There is no 6146 plate current using this method. I would rather stress the Driver tube than the Finals. A lot cheaper tube.

Do this test on all bands. Allow the Driver tube to rest 10 seconds or so between each band as it is running Class A at full plate current (approx 27ma) and will get pretty hot. I have never lost a Driver tube doing this test, but it is possible especially if the tube is marginal to begin with.

If you have a good Driver stage and good alignment you should attain FSD ALC indication with the Car Level pot advanced no more than 1200 (typically between 1000 and 1100) with exception of perhaps 10 meters on the earlier rigs.

I often get rigs here that require CAR level pot settings at 1300 to 1400 to get FSD indication on all bands. Easy to fix this.

> switching diode D6 at the Drain of Q4

Ah! Now I know why my head kept taking me back to that diode. I've been following this and chasing down the schematic as the discussion has been going on, for the practice.

(I do that with most of the problems with technical and troubleshooting solutions that come across this list. I'm NOT good at these radios, not yet, being much too far out of practice after twenty-five years of "throw the board away" type 'repairs' in the computer side of electronics. But I intend to get better.)

Shorting that diode will force Q4 to conduct, and if everything else is good (excepting that switching diode, which would more likely fail "OPEN" than "SHORT") the gain should jump up to normal.

Oh, and I opened my 520SE (in the middle of the bleedin' night; insomnia is good for something, but I don't recommend it for troubleshooting) and located the switch deck, the J14 / JAS point. THAT took a little while, but I did find it and verified that it was the correct point on the switch deck. I checked at the S5-6 and S5-7 points, to be sure there was no corrosion causing resistance on the wafers or anything, too.

ON the WWV setting (which is working - I get a good WWV signal when I put even a 2-meter whip on the antenna plug) the meter shows 13.5 VDC at both points. That's going to be plus or minus 0.2 VDC due to meter error and with my best-guess calibration. But the voltage there is definitely at least 13 volts, very likely a bit higher.

(I don't have a voltage standard that is all that good. I used four different meters - 3 of them digital - and two different batteries to get an average reading of the batteries, then applied that to the analogue Heathkit VTVM calibration. Did the same again using a bench power supply and then for AC, just line voltage out of the wall for higher ranges. Low range, best I can do is 0.2 VDC. and that's probably wishful thinking despite doing the best I could with what I have.)

Thanks Joe. I have no idea how long this has been sitting. After reading the posts here every day, I agree with you that a good cleaning is probably the next step. I will order some DEOXIT from my

favorite supply house. Your advice about using a camera to document everything is good advice, thanks.

After playing around with it, I think the AF amp is working but it has nothing to amplify. I checked the RF gain and it is turned all the way clockwise. I will get back to the group after I clean it out.

Thanks for everyone’s advice. It is much appreciated.

Tom

Tom,

Ok...no problem. The "remote socket" is indeed used for linear amplifier control. There is no need to have anything plugged into this unless it's being used to operated an amplifier.

I understand you got the rig from a now SK. How long had it sat around without being used? These rigs don't like to sit around and not be used. Various controls, pins, sockets...etc. will
get corrosion and other "junk" on them. Many times, a good cleaning of ALL pins, sockets, controls..etc is a good first step. As others here may attest also...many problems have been
"fixed" by a good cleaning of the above stated items. I use DEOXIT D5...available at Radio Shack.(arrg)...any good electronic supply house, some times it can be found at a good music store...one that sells guitar amp..especially, or mail order....canned air or "air duster" can be found a computer stores, office supply stores...and Walmart.

Have you double checked position of ALL controls...especially the RF gain? That's a common "whooops."

If you do decide to clean all the "stuff"...TAKE NOTES/PICTURES or draw diagram of what plug you removed from where or what...especially the IF board! Use a "sharpie" to label connectors works too.

Good luck...keep us posted

Tom,

If your rig has the "shorting plug" and has only 2 pins, #'s 8 & 9 "connected together," that is correct.

Look in the "operators manual." It shows you the info you need.

Make sure that the RF GAIN control is turned FULL RIGHT...or full clockwise to start.

Also make sure that the "cal" function is not turned on.

Since you do not know the whole history of this rig...the "golden screwdriver" may have been used.

Suggest you review the "operators manual" and take a look at the "service manual" also. Setting the zero or resting position of the "S" meter is not hard...but the S-9 setting requires
input from a signal generator...but at times can be "fudged" at bit after a basic IF/RF alignment...which is covered in your "operators manual."

Wes

Thanks for looking at the "normal" voltages at J14 and JAS for Adrian. Your 13.5vdc is more like what I would expect rather than the high 11 vdc that he is reporting. He likely needs to change the Pi filter electrolytics.

So the question remains what will the gain of the dual gate mosfets look like with 12vdc as opposed to 13.5vdc applied? I dont think as drastic a reduction as he is seeing. If switching diodes are good they will turn on with 12vdc applied. I see approx 3.3k resistor limiting the current so only about 3.6 ma of forward current. So not turned on very hard with either 12vdc or 14vdc foward bias. As you note if open then he would experience the loss of signal level he is reporting.

If you look at Q5 and Q4 you will see that they employ "self-bias" using 100 ohm Source resistors so all they need is Drain voltage to amplify and function as mixer. I dont think a problem with Q8 Het Osc as he reports some level of 15mhz copy so Q8 must be oscillating and providing some level of 23.895mhz local oscillator signal to Q4 Mixer..

Here in the states if a person doesnt have a bench supply they can go to Walmart or the Dollar Store and buy cheap 6vdc and 1.5vdc lantern batteries and have a source of DC for testing. Two 6vdc and one 1.5vdc in series makes a nice clean 13.5vdc supply with decent ampacity. Most of this power supply substitution is at very low current so these batteries will last about as long as shelf life. Just have to store them in container that would contain electrolyte should they develop a leak. Very corrosive. .

It is pretty rare for these switching diodes to fail, but relatively easy to jumper them to see if normal signal is restored.

WIth decent RF sig gen these kinds of problems can be pretty quickly isolated to a stage or device. Biggest trick is getting on test points on component side of the boards to inject and measure.

Thanks again for your help. I have pretty much exhausted any help I can give Adrian. If you see something jump in.

Terry K9TW

> switching diode D6 at the Drain of Q4

Ah! Now I know why my head kept taking me back to that diode. I've been following this and chasing down the schematic as the discussion has been going on, for the practice.

(I do that with most of the problems with technical and troubleshooting solutions that come across this list. I'm NOT good at these radios, not yet, being much too far out of practice after twenty-five years of "throw the board away" type 'repairs' in the computer side of electronics. But I intend to get better.)

Shorting that diode will force Q4 to conduct, and if everything else is good (excepting that switching diode, which would more likely fail "OPEN" than "SHORT") the gain should jump up to normal.

Oh, and I opened my 520SE (in the middle of the bleedin' night; insomnia is good for something, but I don't recommend it for troubleshooting) and located the switch deck, the J14 / JAS point. THAT took a little while, but I did find it and verified that it was the correct point on the switch deck. I checked at the S5-6 and S5-7 points, to be sure there was no corrosion causing resistance on the wafers or anything, too.

ON the WWV setting (which is working - I get a good WWV signal when I put even a 2-meter whip on the antenna plug) the meter shows 13.5 VDC at both points. That's going to be plus or minus 0.2 VDC due to meter error and with my best-guess calibration. But the voltage there is definitely at least 13 volts, very likely a bit higher.

(I don't have a voltage standard that is all that good. I used four different meters - 3 of them digital - and two different batteries to get an average reading of the batteries, then applied that to the analogue Heathkit VTVM calibration. Did the same again using a bench power supply and then for AC, just line voltage out of the wall for higher ranges. Low range, best I can do is 0.2 VDC. and that's probably wishful thinking despite doing the best I could with what I have.)

Terry thanks for such a complete answer to my query re the switching diodes, and for more troubleshooting suggestions. It's great to learn more about these rigs as well as get nearer to solving an issue. We'd thanks for measuring voltages at times above and beyond call of duty! I am working away from home now so can't try going down signal chain with sig gen (protected against DC with the cap) - and jumpering diode at Q4 - till weekend now but am looking forward to it with all the great help here. I do have schematics with me on my iPad so can at least get familiar with the path and the RF board x-ray so I'm all set when time comes. Terry I can see on schematic that the marker is injected right at the antenna as you confirmed. 73 guys and I'll report back in a week! Adrian G4IQW

I can tell you, my early TS520 does not like to sit about and if I haven't had it on for a week everything is very scratchy and intermittent until it gets good and warm.

The solution, of course, is to throw a few buckets of electrons at the sky every day.

Well, thank you all for the great info. It is greatly appreciated. I have respect and admiration for all the time and knowledge you put into a great hobby and this forum. TANK YOU. Jerry K4GEW

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Agree Tanks are pretty hardy as long as dont have long off resonance key down times. Even then they can handle the elevated plate current for some time. Just no reason to stress them needlessly.

Quickest way to have instant 6146 failure is to have thermal run-away from loss of operating bias. Dirty bias pot can cause this when attempting to set 60ma zero signal current. Some people deliberately test the finals by adjusting the bias voltage and run Ip up to 350ma. I do not recommend this. It is a needless static dc test that tells you nothing about how tube works with RF drive.

The Drive control position for Rx and Tx can be out of sync if coil pack alignment is not done correctly. I see this regularly.

There is no reason to stress the 6146 finals when testing the Driver stage. Just simply turn off the SG switch. Now in CW mode with 6146 heaters on you can peak the Drive control and increase the CAR level pot for full scale ALC indication. Leave rig keyed for a few seconds and if you can attain FSD and it does not slowly drift off you know Driver stage is good. There is no 6146 plate current using this method. I would rather stress the Driver tube than the Finals. A lot cheaper tube.

Do this test on all bands. Allow the Driver tube to rest 10 seconds or so between each band as it is running Class A at full plate current (approx 27ma) and will get pretty hot. I have never lost a Driver tube doing this test, but it is possible especially if the tube is marginal to begin with.

If you have a good Driver stage and good alignment you should attain FSD ALC indication with the Car Level pot advanced no more than 1200 (typically between 1000 and 1100) with exception of perhaps 10 meters on the earlier rigs.

I often get rigs here that require CAR level pot settings at 1300 to 1400 to get FSD indication on all bands. Easy to fix this.

> Thanks again, Jerry K4GEW

These old tanks are pretty tough, and if the radio is basically healthy and you're tuning up into a dummy load (ie. no reflected power) and only using short bursts of trasmit, it's hard to get it wrong.

I wanted to test the transmit frequency stability of my TS-520 so I ran it into a chunky great 250W Rohde and Schwarz dummy load (looks like an old-fashioned heating radiator, only a little smaller than the 520) for a good ten minutes. At 80W output the output valves were just about warm. I did have my hand on the SEND switch ready to chop the power in the event of any distress, but I needn't have worried. I don't recommend you try this, unless you know everything in the PA cage is utterly beyond reproach.

Just keep your hand on the SEND switch, check your dummy load isn't trying to melt its way to China, and don't do anything silly.

Oh, and the DRIVE control also functions as the RX preselector tuning, so if you tune on receive for the strongest signal (or most noise) you'll be about the right place for peaking the DRIVE control on transmit.

Hate to stick my nose in here, but have a suggestion:

Assuming that the S-meter is pegged full scale with RF gain pot full CW then you have lost the voltage to the AGC bus line or there is a fault on it pulling it down.

How comfortable are you working inside the radio?

Do you have a multimeter of some type to take some voltage readings?

Before taking voltage measurements you can try removing and cleaning the Aux Relay contacts on the Relay Unit Board on bottom side of the rig. This board has the Aux relay in a socket and the 14vdc filter caps on it.

This relay switches the AGC and ALC bus lines and common problem is dirty contacts.

With rig down powered and unplugged you can remove the covers and pull Aux Relay and remove its plastic cover and clean the contacts by pulling strip of copy paper wetted with Deoxit thru both the NC and NO contacts applying light pressure to the armature.

If cleaning the contacts of the Aux relay does not restore your AGC bus voltage then we can talk about measuring RF-1 voltage at IF board and if need be at the AVR board.

Tom,

Ok...no problem. The "remote socket" is indeed used for linear amplifier control. There is no need to have anything plugged into this unless it's being used to operated an amplifier.

I understand you got the rig from a now SK. How long had it sat around without being used? These rigs don't like to sit around and not be used. Various controls, pins, sockets...etc. will
get corrosion and other "junk" on them. Many times, a good cleaning of ALL pins, sockets, controls..etc is a good first step. As others here may attest also...many problems have been
"fixed" by a good cleaning of the above stated items. I use DEOXIT D5...available at Radio Shack.(arrg)...any good electronic supply house, some times it can be found at a good music store...one that sells guitar amp..especially, or mail order....canned air or "air duster" can be found a computer stores, office supply stores...and Walmart.

Have you double checked position of ALL controls...especially the RF gain? That's a common "whooops."

If you do decide to clean all the "stuff"...TAKE NOTES/PICTURES or draw diagram of what plug you removed from where or what...especially the IF board! Use a "sharpie" to label connectors works too.

Good luck...keep us posted

Tom,

If your rig has the "shorting plug" and has only 2 pins, #'s 8 & 9 "connected together," that is correct.

Look in the "operators manual." It shows you the info you need.

Make sure that the RF GAIN control is turned FULL RIGHT...or full clockwise to start.

Also make sure that the "cal" function is not turned on.

Since you do not know the whole history of this rig...the "golden screwdriver" may have been used.

Suggest you review the "operators manual" and take a look at the "service manual" also. Setting the zero or resting position of the "S" meter is not hard...but the S-9 setting requires
input from a signal generator...but at times can be "fudged" at bit after a basic IF/RF alignment...which is covered in your "operators manual."

Hi Terry,
I am still alive. Not (yet) electrocuted. had to do something else no hobby related...

I am using a simple home made RF probe consisting of 2 x 100 ohm 5 W resistors in paralell an a 1n34 germanium diode with a 100nF cap... That thing I am also using for checking my SW20+ QRP 20 meter TRX (Small Wonder Labs). And that's working FB. And because there is not much RF power coming from the 520 when the SG is off. I can use that one.

Wally/Pa3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally:

Yes for any band that you are getting RF output power as seen on RF position of the panel meter or on an external wattmeter then you have to have RF drive at the
control grids of your 6146 finals. If you have RF drive then you have to have feed thru power from the control grids to the plate circuit thru that 0.22pf Cgp.

If you try neutralizing on 40 meters will see feed thru power, but will be lower than what I gave you for 10 meters. Probably a high of approx 270mv and low of approx 20mv. If using a single germanium diode probe then might just see slight meter indication as the diode barrier will be approx 250mv.

What kind of RF probe are you using?

Terry

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Ok Terry,
All understood.
Will check it tomorrow.... but what I still don't understand is, that the rig is working FB on 7 mhz and higher,
So it must have drive on pin 5 otherwise it wouldn't work at all.... right?

but will check it and let you know the outcome..

Many thanks for spending your time to answer me... very much appreciated

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at 28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig

and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.
The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.

As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

OK with this type probe then you dont need a dummy load connected to the SO-239 connector to perform neutralization as long as you have the SG switch off.

I am assumng the 50 ohms is connected in shunt and your diode is in series so you will read the voltage drop across the paralleled 100 ohm resistors in the probe.

Kind of unusual config as most commercial RF probes use a series dc blocking cap, a shunt diode, and a high value of series meter multiplier resistor so that it will read close to rms value on your 10 meg DMM or 11 meg VTVM.

As long as have good 1N34 then your probe will work.

Hi Terry,
I am still alive. Not (yet) electrocuted. had to do something else no hobby related...

I am using a simple home made RF probe consisting of 2 x 100 ohm 5 W resistors in paralell an a 1n34 germanium diode with a 100nF cap... That thing I am also using for checking my SW20+ QRP 20 meter TRX (Small Wonder Labs). And that's working FB. And because there is not much RF power coming from the 520 when the SG is off. I can use that one.

Wally/Pa3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally:

Yes for any band that you are getting RF output power as seen on RF position of the panel meter or on an external wattmeter then you have to have RF drive at the
control grids of your 6146 finals. If you have RF drive then you have to have feed thru power from the control grids to the plate circuit thru that 0.22pf Cgp.

If you try neutralizing on 40 meters will see feed thru power, but will be lower than what I gave you for 10 meters. Probably a high of approx 270mv and low of approx 20mv. If using a single germanium diode probe then might just see slight meter indication as the diode barrier will be approx 250mv.

What kind of RF probe are you using?

Terry

Ok Terry,
All understood.
Will check it tomorrow.... but what I still don't understand is, that the rig is working FB on 7 mhz and higher,
So it must have drive on pin 5 otherwise it wouldn't work at all.... right?

but will check it and let you know the outcome..

Many thanks for spending your time to answer me... very much appreciated

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at

28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.

The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.
As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

ACTIVATE the PTT and measure between the black and each of the other color wires, with an ohm meter set to low resistance scale, to see what one keys the transwmitter. Black is probably ground. the remaining wire is the mic audio.

Terry & Tom,

Terry, no problem about "sticking your nose in." You brought forth sound statements and, your knowledge and expertise are...in my opinion anyway....most EXCELLENT

The poster, I think, is unfamiliar with these fine old rigs, and possibly some diagnostic equipment.
But that's why we are here. I wanted to start out simple...and progress slowly...and get "more in depth" as the thread continued.

Terry, thanks for being a mentor and group member

Tom, Terry's statements are based on sound diagnostic logic. But, let's start at the bottom..get the rig "cleaned up" as stated in prior posts...and go from there.

Richard,

It is likely that white is mic hi, the shield is mic lo. Black is PTT ground and red is PTT. If you are wiring it for Kenwood 4 pin rig it is suggested to keep the mic and PTT grounds separate to reduce the chance of hum. Sometimes you can not avoid connecting the shield to PTT ground if the shield is grounded to the mic frame.

If the wiring is as I suggested above then use the following wiring for the plug:
Pin 1: White (mic hi)
Pin 2: Red (PTT)
Pin 3: Black (PTT ground)
Pin 4: Shield (mic lo)

Depending on your particular base, the attached link may help. You can see the same cable and color codes you describe.

Most D-104s, including the amplified model/base, has the wiring and switch diagram on the inside bottom cover. Did you check the bottom cover plate?

If I may ask, are you going to use the amplified D-104 with your KW hybrid and if so, which KW hybrid model?

I see I missed the KW hybrid model in the subject line, you're using it with a TS-520.

Are you aware the amplified D-104 has a "low impedance" spec and the TS-520 has a "high impedance" specs? Using the amplified D-104 with a TS-520 will result in a microphone impedance "mismatch" which will effect how your transmit audio sounds. Also if you turn the amplifier in the base of the D-104 up so you sound "louder" at the receive end or an attempt to overcome the impedance mismatch, this could easily lead to over driving the speech amplifier in the TS-520 leading to distortion in your transmit audio.

Im going to use the mic with my 520S and 530S. Wiring info seems to be a real secret on the internet for these radios and this mic LOL

I believe the D-104 mic also had the wiring schematic on the inside of the base plate/cover.

Hi,

This is a very good site with mic information.

You will also find schematic for the Astatic D-104

http://www.qsl.net/g4wpw/date.html

Richard

I have the orginal schematic for the D-104..

Send a email to kj6ix@arrl.net and I will shoot it your way

73's Dale

---In TS-520_820_530_830@yahoogroups.com, <wa2lbi@...> wrote:

Richard,

It is likely that white is mic hi, the shield is mic lo. Black is PTT ground and red is PTT. If you are wiring it for Kenwood 4 pin rig it is suggested to keep the mic and PTT grounds separate to reduce the chance of hum. Sometimes you can not avoid connecting the shield to PTT ground if the shield is grounded to the mic frame.

If the wiring is as I suggested above then use the following wiring for the plug:
Pin 1: White (mic hi)
Pin 2: Red (PTT)
Pin 3: Black (PTT ground)
Pin 4: Shield (mic lo)

Depending on your particular base, the attached link may help. You can see the same cable and color codes you describe.

You say the mic works in VOX mode so you are making progress. Did you verify with an ohm meter that the red and black are the PTT circuit? It is possible that there is an issue with the mic switch(es). It is also possible that somebody has changed the wiring. Maybe they wired it so that PTT ground is the shield and the red or back is the PTT line. You need to do some work with the ohm meter.

Maybe I missed this if you stated it earlier but did you verify that the rig keys when you short pins 2 and 3 on the mic jack or do you have another mic that works in PTT mode on the rig? If the rig isn't keying with a short on pins 2 & 3 or with a known-good mic then get the rig fixed before you work on the mic.

Keep us posted!

Well, I just found the problem. Seems there is a short or break in the mic cord right where it goes into the base, inside the strain relief. The correct wiring is:

1- white
2- red
3- black
4- shield

I had to dig out the ohm meter, my blood pressure was starting to go up lol

You need a TS-520S manual!

The 520 has a 4 pin mic connector. Two pins are for the mike element. The other two are for the switch.

Connect an ohm meter to the red and black leads then push the switch.

There is a mike wiring diagram in the 520 manual.

I now know why this mic had a $5 price-tag at the garage sale where I bought it. It has a break in the cord, a resistor had one leg out of its hole in the pc board, and I also replaced the 5mf electrolytic just because. Now its working great.. lol

Hi guys,

Can anyone tell me what wires go on what pins for the connector on my D104? Im using a D-104 with the TUG8 amplified stand. It has 3 wires and a shield. Colors are red, white and black. I keep hearing something about keeping grounds separate to prevent hum. Can anyone tell me where the wires go?

Thanks,

Richard, KD8HMO

Topic: 46087 Message: 46107

I dont call cleaning aux relay contacts getting in "depth".

There are lots of people who preach cleaning all molex connectors on these KW hybrids rigs to resolve any and all operational issues and often get lucky and affect a fix, but they have no idea what was wrong and what fixed it.

However any time you start pulling/cleaning molex connectors you risk damage. This is especially true with the TS530 and TS830 radios. Very easy to pull molex connectors off the boards. Now risk lifting foils and pads in the repair process on old phenolic boards.

It bemuses me that so many still dont understand what a pegged S-meter is telling you after all the time that has been devoted to explaining how the AGC and S-meter circuit functions in the rigs.

I saw only one "basic" suggestion on this thread and that was to make sure RF gain was full CW position. A common operator error that anyone could make.

He can have a ball pulling all the molex connectors off his TS-820. Not something I would advise him to do.

One thing I have learned with many vintage rigs it is easy to induce new faults and some of those will be latent faults when you disturb things that are not broken.

For me I prefer to troubleshoot.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <stilesjoseph@...> wrote:

Terry & Tom,

Terry, no problem about "sticking your nose in." You brought forth sound statements and, your knowledge and expertise are...in my opinion anyway....most EXCELLENT

The poster, I think, is unfamiliar with these fine old rigs, and possibly some diagnostic equipment.
But that's why we are here. I wanted to start out simple...and progress slowly...and get "more in depth" as the thread continued.

Terry, thanks for being a mentor and group member

Tom, Terry's statements are based on sound diagnostic logic. But, let's start at the bottom..get the rig "cleaned up" as stated in prior posts...and go from there.

Hello to the group,

Long time member, first time poster.
Some background on me. Licensed about 12 years ago, Call is W7OA, name is Tom, and I'm in Reno, NV. I enjoy working on / restoring older radios / amps, mostly from the tube era and have worked on, (and own - much to the XYL's chagrin), a fair number. I have worked on a few hybrids, both Kenwood and Yaesu so not totally out of my depth here - I hope. I would consider I have decent troubleshooting skills and a fairly well equipped bench.
So, on to my problem: A TS-820S I'm bringing back to life is now working fine except for an issue with the dgital display. The display works properly on all bands except the four 10 meter band segments. On these segments the display wanders around apparently randomly, showing around 23. xxx or 24.xxx mhz. The receiver is however receiving on the proper frequency, as checked with a SG. Also oddly, once properly loaded up for transmit, the display shows the proper frequency while transmitting, and reverts to random numbers during receive. This is the case on all four 10 meter segments.
I'm hoping someone in the group has come across this or a similar problem before and can give me a shortcut in the right direction.
Thanks for any help.
W7OA

Tom: Once I came across a similar problem with my friend's 820. Erratic display was there on all bands. More than likely the problem is caused by dirty contacts in various areas within the 820. I think a good cleaning is in order for your 820.
I cleaned the CAR,PLL and COUNTER units and problem gone.These units have 2 PC boards inside each metal enclosure. The boards are connected together inside each metal enclosure through a set of fix pins inside the metal enclosures. Quite often the connections between the internal PC boards become corroded resulting in poor connection. Removing each unit and cleaning the connections inside the metal enclosures, more often than not, fixed the problems you are experiencing.

Hi gents, the problem lies in the vias (connections between top and bottom of the board(s) in the display unit. Fought mine, finally soldered bus wire through each via after sucking out the solder, resoldering each via.
Pretty sure well known problem with the 820 display units.
Has worked 100% ever since. Not a bad job, but I am an electronic tech and deal with issues like this daily.

470k sounds more right that 410k. Aren't they just bleed resistors? I doubt they're in any way critical.

R1 thru R4 are NOT bleeder resistors. R1 thru R4 on the Rectifier Unit board are reverse voltage equalizing resistors to protect the series connected diodes, D1 thru D4, against reverse voltage spikes that could damage any of the individual diodes D1 thru D4.

Mouser sells various 470K 1/2 watt resistor but since R1 thru R4 are used in the Rectifier Unit's HV supply, the voltage rating of the resistors used should be taken into consideration. Not all resistors, even resistors of the same power rating, have the same voltage rating.

Mouser sells a 470K 1/2 watt 1% metal film resistor with a voltage rating of 500 volts, part number "71-CMF60470K00FHEK", for 30 cents each.

If you are replacing any of the 4 resistors, R1 thru R4, I recommend you replace all 4 resistor together as a group, even if only one or two resistors are found to be bad or out of tolerance. You want each resistor to be as close in resistance as possible and I believe these 1% resistor will fill that requirement.

Now, my questions are

1. Why are you replacing the Rectifier Unit resistors R1 thru R4?
2. Are they blown, burnt/cracked, or what?
3. If they are burnt/cracked, then have you checked each filter capacitor, C21 and C22, to determine if they too should be replaced as well?
4. Have you checked diodes D1 thru D4 to see if they are bad/blown "open"?

Jim,

  The "D" model I believe, was a non-export Japanese model only. I think that it was originally wired for 100V, not the common 120V here. Also, I think that the output power was limited to maybe 50W output. Since quite a number of our military were in Japan..many may have made it here and been "converted" to 120V. I have never seen one up close.

Oh yes, that's right. I didn't have the manual in front of me at the time.

Bingo. It smacks a bit of the "it's not working, must replace all caps" mentality...

If you have not performed the procedures in Kenwood's #54 tech bulletin, that would be a good place to start. You can view it here:

http://wb4hfn.com/KENWOOD/Articles/SERVICE%20NOTES%20-%20ALL%20HYBRIDS.pdf

It's a good idea to put a piece of wire, like what you would find on an 1/8 watt resistor lead, through the plated through holes and solder both sides. There are probably 15-20 of these that this needs to be performed on.

Regards,
Mark, WB0IQK

Hello to the group,

Long time member, first time poster.
Some background on me. Licensed about 12 years ago, Call is W7OA, name is Tom, and I'm in Reno, NV. I enjoy working on / restoring older radios / amps, mostly from the tube era and have worked on, (and own - much to the XYL's chagrin), a fair number. I have worked on a few hybrids, both Kenwood and Yaesu so not totally out of my depth here - I hope. I would consider I have decent troubleshooting skills and a fairly well equipped bench.
So, on to my problem: A TS-820S I'm bringing back to life is now working fine except for an issue with the dgital display. The display works properly on all bands except the four 10 meter band segments. On these segments the display wanders around apparently randomly, showing around 23. xxx or 24.xxx mhz. The receiver is however receiving on the proper frequency, as checked with a SG. Also oddly, once properly loaded up for transmit, the display shows the proper frequency while transmitting, and reverts to random numbers during receive. This is the case on all four 10 meter segments.
I'm hoping someone in the group has come across this or a similar problem before and can give me a shortcut in the right direction.
Thanks for any help.

Topic: 46087 Message: 46129

Gentlemen:

You are all being a big help here. I did study electronics back in the 70's when troubleshooting discrete components was all there was. TTL and the 555 timer were advanced stuff. I still have an old Heath kit oscilloscope

that I bought and assembled in the early 80's. I have been repairing PC's for a while lately. So, I am familiar with some test equipment. the advantage of giving this a cleaning first, is it lets you familiarize yourself with the

transceiver and locate different sections of the schematic in the radio. I think just that will be a good start to my troubleshooting. My Deoxit arrived today so I will be able to do some cleaning as I study this rig.

I'm starting to think that "quick question" was not an appropriate name for this thread..

Happy Thanksgiving to you folks in the states and once again, THANK YOU for all your assistance.

Tom

Subject: [TS-520_820_530_830] "quick question" thread

Terry & Tom,

Terry, no problem about "sticking your nose in." You brought forth sound statements and, your knowledge and expertise are...in my opinion anyway....most EXCELLENT

The poster, I think, is unfamiliar with these fine old rigs, and possibly some diagnostic equipment.

But that's why we are here. I wanted to start out simple...and progress slowly...and get "more in depth" as the thread continued.

Terry, thanks for being a mentor and group member

Tom, Terry's statements are based on sound diagnostic logic. But, let's start at the bottom..get the rig "cleaned up" as stated in prior posts...and go from there.

I have had this problem too Tom with my much modified TS820s. In my case
the bands affected were 21 and the 28 MHz ranges. Oddly enough the 24
and 18 MHz WARC bands were OK (my unit is modified for WARC).
Now there is a mod on the mods.dk site which involves putting an extra
tuned circuit in the synthesiser to remove a potential spurious signal.
This works, up to a point, but clean contacts are also a good idea.
However I am pretty sure that the chip used to combine the various
signals is no longer up to scratch. Problem is (of course) 1970's IC's
are even more made of "unobtanium" than 1970's tubes!!!

Thanks for all the information regarding this model. One good clue about this rig is that it's badged "Trio" instead of "Kenwood". One just showed-up today on Fleabay which got my attention and why I posted the question. Received but no transmit. It went pretty fast under "Buy It Now" for two-hundred bucks including shipping and I'm glad I passed it up even though I'm a big fan of the older Kenwood hybrid rigs. Sure enjoy using my "D-Twins".

D for Domestic. NON-EXPORT model of the 820, for the Japanese market.

Some have come across the pond, mostly via U.S. military members, they were available fairly cheaply in the after-market in the mid- to late-80's when I was stationed in Misawa Air Base, Aomori Prefecture, on Honshu.

(Also Known As "The Great White North," 6 to 8 meters of snowfall a year where I was, on average. In 1986 the snowfall was almost double the average, all told.... For some reason everyone thinks of Japan all being like Okinawa, a tropical paradise. Not only is Japan NOT all tropical, Okinawa is NOT even Japan - MOST DECIDEDLY NOT! Japan, I was there the day the Japanese government raised the Japanese flag (instead of the Okinawan flag) over the Okinawan Diet (Congress, sort of) for the first time. I thought they were going to burn that whole island down...)

As for the differences in the radios, S vs. D series, I can only go by memory, but the memory is that there is NO difference excepting the power supply section. The transformer in the D models was for 100 volt Japanese power, and it accepted both 50 and 60 Hz frequency line voltage. Converting them to "S" model was mostly a swap of the transformer and some fuses, I believe. Possibly a few other odds and ends, but the primary winding was the big change in the D series radio versus the S model.

Japanese power is a whole 'nother topic all its own.

The big kicker, is that part of Japan is on 50 Hz, the rest on 60 Hz. Most non-power-line-synched devices just cope with the difference in frequency, and a large portion of U.S. market general electrical and electronic gear will run just fine on the Japanese current. The majority of small devices sole inside Japan have a "50/60" Hz frequency switch which must be toggled to the correct value, depending upon where you are in the country. (AC synchronous motors in clocks for instance, rely on the frequency of the power line current to stay 'on time' and CAN NOT just be expected to work properly when fed current of a different frequency.)

A lot of stuff will "just work" in Japan, if it was made for the U.S. market. But NOT everything.

Woe betide (s)he who plugs a resistive-element hair dryer meant for 60 Hz 120 VAC power (Stateside) into a Japanese 50 Hz 100 VAC socket. (The plug will quite likely FIT, too!) The cloud of smoke is not only large, but -rather- smelly, and the hair 'dried' with it will smell of burned insulation for - and I am absolutely not joking here - SEVERAL DAYS! If the hair did not catch fire and burn mostly OFF, that is.

My ex-wife lost a hair dryer in a Tokyo motel that way, when she was new to the country..... About burned the motel room down, too. She was quite frazzled when I got there to pick her up and get us both on the train back to base, on the other end of Honshu. And FRIZZLED, too! Didn't burn her hair off, quite, but it was a bit crispier than the day before.

KENWOOD TS-520_820_530_830Hi all--
I’m a fairly new ham (first ticket this year), but have a electrical engineering background and am comfortable debugging circuits and soldering. However, I have very little experience with fixing hybrid rigs like the Kenwood (although I have both a TS-520 and TS-820S, my primary radios).
I recently picked up a TS-820S, and it works great except that I am getting lower than expected output on both USB and LSB on all bands. (CW power at 100 watts-120 watts; SSB output only puts out about 15-25 watts; for comparison, my TS-520 tuned up to the same CW power level will often read 75-100 watts on SSB on the same power meter). With Compression turned on have the same problem. ALC metering as expected. Full output on CW and CAR control allows me to adjust levels for the full range in CW.
I thought this esteemed group might help point me in the right direction before I spend a lot of time poking around the innards of the radio.
Base on the schematics, I am guessing that there might be issues at Q20 or Q21 causing low output on SSB. Am I on the right track? Also, anything I ought to know about replacement transistors for either or both of these 2SC733’s? Or, is there something else I should be looking at?
Thanks (and happy Turkey day!)
Ben

Ben,

You say your TS-520 produces 75 to 100 watts output as indicated on your watt meter in "SSB" (USB or LSB) mode? What make and model watt meter are you using that displays that power output level from your TS-520 in sideband transmit? Also what indications are you seeing on the meter (meter switch set to ALC) during voice peaks in USB or LSB mode with 75 to 100 watts output indicated on your watt meter?

The TS-520's normal DC input power (CW mode) is 160 watts (.2 x 800 = 160). Typical final amplifier efficiency rating (output power verses input power ratio) is between 55% and 60%. If we lean more towards the 60% efficiency rating, the CW carrier power output into a 50 ohm load from your TS-520 will be approximately 96 watts (.6 x 160 = 96).

You then say your newly acquired TS-820S is producing similar 75 to 100 watts CW carrier output power but in SSB (LSB or USB) it is only indicating 15 to 25 watts output. That appears to be normal power output on voice peaks from your TS-820S when output is fed to an average watt meter.

Again, what make, model, and type of watt meter are you using, Peak reading or average power?

KENWOOD TS-520_820_530_830Mike,

Thanks for the reply.

The watt meter I am using is the MFJ 949 (wattmeter built into the MFJ Deluxe Versa Tuner). I'm not sure if it's calibrated, how accurate, or how well it works, but usually both rigs end up right at around or above 100 watts peak reading on the meter in CW mode when tuned up using the procedures in the manual. Idle current set to 60ma on both rigs, if the IP meter is correct. Drive tuning to peak ALC, plate tuned to minimum current.

The readings I am seeing in SSB are peak readings after following tuning procedures.

ALC meter indications are per the tuning procedures for voice, with MIC control adjusted to peak ALC on the upper end of the ALC indicator on the dial in both cases. For both rigs, that ends up being a MIC level of 3.

For the 820S:
in TUN mode, ALC peaked, IP reading around 65ma (manual indicates this should be 100ma)
in CW mode, IP reading only around 75ma (manual indicates this should be 200ma)
In LSB or USB, IP reading 60ma to 130ma (manual indicates range should be 60 to 250ma).
No idea what this would indicate. My (TS520, for comparison, is showing TUN peak of 50ma, CW of 200ma, LSB of 60ma to 130ma).

The only reason I ask is the peak readings on SSB are significantly different between the 520 and 820S, with the same CW output level, and in some testing with some very local stations on 40m (ie across town) they are able to hear the difference in output power. I am assuming (perhaps incorrectly) that the two rigs would have a somewhat similar power output profile??

Thanks,

Ben

Topic: 46139 Message: 46145

Ben,

I assume you have set the MFJ-949 watt meter "Peak/Average" switch to "Peak".

I don't know what you mean when you say:

"/*For the 820S:
in TUN mode, ALC peaked, IP reading around 65ma (manual indicates this should be 100ma)
in CW mode, IP reading only around 75ma (manual indicates this should be 200ma)"

*/It is true the DRIVE control is adjusted for a peak ALC meter indication in TUNE mode then the meter switch is set to IP and the PLATE control is adjusted for a "dip" in IP current. However, you say the IP meter reading is 65ma which is normal but you say the manual says it should be "100ma". I don't know where you read that, I have looked at the 820 operator's manual and I can't find where it says that.

The following is how you initially set the Class AB1 60ma idling current using the bias pot adjustment, followed by how to tune the transmitter on any band. The MFJ-949 has an internal 50 ohm "300 watt" dummy load so I recommend you get use to using it when tuning up your transmitters.

Setting the final amplifier's bias pot for Class AB1 60ma idling current:

1. Connect the 820 to a 50 ohm dummy load.
2. Set the Mode switch to either USB or LSB (it doesn't matter which sideband, LSB or USB, you use), MIC gain control fully CCW, and the meter switch to IP.
3. Flip the SEND switch UP (keys the transmitter) and adjust the bias pot on the rear panel so the meter points to 60ma (top scale) then flip the SEND switch DOWN (unkeys the transmitter).

This concludes the final amplifier's 60ma idling current setting. You should not have to adjust the bias pot in the future unless you change final tubes or you have performed service on the final amplifier. You do not have to adjust the bias pot if you change the driver tube only.

Next is the tune up procedures (820 is still connected to the 50 ohm dummy load):

1. Set LOAD control fully CCW
2. Set PLATE control knob so it points to the middle of the white silk screen band arc above the PLATE control based on the band selected by the band switch.

3. Set the Mode switch to TUNE
4. Set the Meter switch to ALC
5. Set the CAR control knob so it points between 10 and 11 o'clock.
6. Flip SEND switch UP (keys the transmitter) then adjust the DRIVE control for a peak meter indication (ignore ALL meter scales!!). If while adjusting the DRIVE control, the meter pegs full scale to the right, rotate the CAR control CCW so the meter pointer is pointing at 12 o'clock then continue adjusting the DRIVE control for a peak meter indication, again "ignoring all meter scales".
7. Set meter switch to IP.
8. Adjust the PLATE control for a dip in IP current (top scale).
9. FLIP the SEND switch DOWN.

Let the 820 cool down a few minutes.

10. Set the MODE switch to CW
11. Set the METER switch to RF
12. Flip the SEND switch UP
13. Adjust both the LOAD control and the PLATE control for a peak meter indication, ignoring ALL meter scales. If the meter pegs full scale to the right adjust the "RF VOLT" pot on the rear panel for a meter indication that points between 1 and 2 o'clock then continue adjusting the PLATE and LOAD controls for a peak meter indication. The RF meter is not a watt meter. It simply displays "relative" power output and there are no meter scales for the RF meter switch position.
14. Set meter switch to IP and adjust the CAR control for an IP indication of 200ma
15. Flip the SEND switch down (unkeys) the transmitter.

You can determine the approximate input and output power, in CW mode, by noting the IP meter and HV meter indications. Multiply the IP meter indication by the HV meter indication will show the "DC input power" in the final amplifier. The final amplifier in the 820, and all of the KW hybrids, operates in Class AB1 so the efficiency percentage is between 55 and 60 percent. Therefore, multiply .55 or .6 by the DC input power and you will calculate the approximate average RF output power at the antenna connector on the rear panel.

You're done tuning the transmitter. If you are using the tuner in the MFJ-949 to feed your antenna and to tune for lowest SWR, do not touch or adjust the 820 transmitter's PLATE and LOAD controls, adjust the tuner controls ONLY for the lowest SWR.

In sideband, set the MIC gain fully CCW, meter switch to ALC, then press the PTT button. Speaking in a normal voice level about an inch or so from the microphone, adjust the MIC gain to the point where the ALC meter just starts to rise above zero then stop adjusting the MIC gain. This will give you some "head room" if you talk a bit louder, a lot of hams tend to talk louder after they make initial adjustments, which should result in the ALC meter to peak at the top end of the ALC scale when speaking slightly louder into the microphone. You should not adjust

the MIC gain that results in the the ALC meter, on voice peaks, remains "constantly" at the top end of the ALC scale. The average power output in sideband indicated on an average watt meter will be between 20 and 25 watts, somewhat higher on a peak reading watt meter. The peak reading watt meter option in your MFJ-949 is activated by pressing the PEAK/AVERAGE meter switch on the right side of the front panel, "in". If this push button switch is not pressed "IN" then the meter is displaying "average" power (see the MFJ-949 manual, page 1, for details).

The CAR control is "disabled" in either LSB or USB modes. The CAR knob controls power output in TUNE and CW mode and is only active in TUNE and CW mode.

The CW socket is a "N.C." socket which means you do not have to have a CW key/plug inserted into the CW socket for the transmitter to produce RF output in CW transmit. A CW key "IS" required to send CW.

What type of microphone are you using with the TS-820? The microphone impedance for the TS-820 is 50K ohms, same as the TS-520.

I misspoke by saying the MFJ-949 PEAK/AVERAGE meter push button switch
is on the right side of the front panel. It's on the "right hand side"
of the cabinet.

I seem not to be able to post from my Gmail account. Is this a common problem?

Has anyone come up with a solution to the TS-830S transmitter ALC overshoot? A Google search netted no results.

Thanks

Jim:

Yes, the thing is sort of working. As to your posts, yes, they do show up.

Eventually.

Even if your posts are not in the "moderator must approve" list, the new "improved" mess that the Yahooligans made of their kludge of a mailing list manager makes things quite problematical.

(Quite frankly my little one-lung MailMan manager running via PostFix under Linux has a higher throughput, from the look of things and figuring against the size of the pipe going into the server. The size they list in their corporate brag-rag, anyway. Their huge pipe is seemingly less efficient than my little one.)

(Why?? My guess? They're working on 'phasing out' the email-only portion of their disservice, and trying to force everyone to the web page instead, which eats a lot more bandwidth than just text. This would be to ensure that they get all the ad revenue possible. Not all they need to make a healthy profit above overhead. All That Is POSSIBLE, whatever it does to the end-users, in true modern-America maximum-corporate-greed fashion.)

And no, I can find nothing to assist you in the ALC overshoot problem in any of the archives I can find to search. Can you describe the problem more explicitly, or point to a better description of it somewhere on another list or site?

Jim,

Since it appears that you are a new member of this group, your posts are "moderated." This means that: one of the Co-owners or, one of the moderators MUST approve your messages/posts PRIOR to them being sent to the groups main message area. This is done to cut down on spam and other interference. The period of time a person is "moderated" depends on them...for example: you are very active and "play by the policies of the group" gets you un-moderated quickly...say 7 days or so. At times even my post have taken 24 hours to get posted. The Co-owners and the Moderators are not here 24/7.

I will check on your message history and, if appropriate, un-moderate you

73 Joe

Hi Terry,
I think we are talking on different freq HI
I am using the RF probe as mentioned on the site from N5ese

http://n5ese.com/rfprobe1.htm

But without the 4,7M ohm. that is indeed with a series dc blocking cap

73Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

OK with this type probe then you dont need a dummy load connected to the SO-239 connector to perform neutralization as long as you have the SG switch off.

I am assumng the 50 ohms is connected in shunt and your diode is in series so you will read the voltage drop across the paralleled 100 ohm resistors in the probe.

Kind of unusual config as most commercial RF probes use a series dc blocking cap, a shunt diode, and a high value of series meter multiplier resistor so that it will read close to rms value on your 10 meg DMM or 11 meg VTVM.

As long as have good 1N34 then your probe will work.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry,
I am still alive. Not (yet) electrocuted. had to do something else no hobby related...

I am using a simple home made RF probe consisting of 2 x 100 ohm 5 W resistors in paralell an a 1n34 germanium diode with a 100nF cap... That thing I am also using for checking my SW20+ QRP 20 meter TRX (Small Wonder Labs). And that's working FB. And because there is not much RF power coming from the 520 when the SG is off. I can use that one.

Wally/Pa3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally:

Yes for any band that you are getting RF output power as seen on RF position of the panel meter or on an external wattmeter then you have to have RF drive at the
control grids of your 6146 finals. If you have RF drive then you have to have feed thru power from the control grids to the plate circuit thru that 0.22pf Cgp.

If you try neutralizing on 40 meters will see feed thru power, but will be lower than what I gave you for 10 meters. Probably a high of approx 270mv and low of approx 20mv. If using a single germanium diode probe then might just see slight meter indication as the diode barrier will be approx 250mv.

What kind of RF probe are you using?

Terry

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Ok Terry,
All understood.
Will check it tomorrow.... but what I still don't understand is, that the rig is working FB on 7 mhz and higher,
So it must have drive on pin 5 otherwise it wouldn't work at all.... right?

but will check it and let you know the outcome..

Many thanks for spending your time to answer me... very much appreciated

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well you can cut the Neutralizing capacitor out and toss over your shoulder and rig should have some RF voltage at the SO-239 in this test configuration (typically a max of 1.0 rms rf volts with Drive control peaked and Plate tank cap adjusted to resonance). .

What you are looking at is the feed thru power from the 6146 control grid to the 6146 anode. This power is the result of the RF drive voltage swing at the control grid causing a small RF current to flow from the 6146 tubes control grid to the anode thru the tubes inter-electrode capacitance or Cgp. Approx 0.22pf capacitor.

It sounds to me like you have no RF drive voltage at the control grid Pin 5?

If you have rig configured as you say and you can peak the Drive control to get full scale ALC meter deflection then should see something on the order of approx 45 rf volts at Pin 5. I would measure this to confirm finals are seeing Drive.

Best to measure this with O-scope or RF Millivolt meter or a multi-diode RF probe.

If you have to use a single diode RF probe need to back down the CAR Level so you dont burn out the diode in the probe. Connect RF probe to Pin 5 at 6146 tube socket and key rig and slowly bring up the CAR level from zero. Do not exceed approx 30 rms rf volts.

If you have RF drive voltage at Pin 5 you have to have RF voltage at the SO-239 unless bad TR relay contacts or bad SO-239 solder connection or bad Plate blocking/coupling cap or bad plate choke. This should not be as you have normal RF output when you load the rig.

After confirming that you have approx 45 rf volts drive at the 6146 control grids move scope or millivolt meter to the SO-239. Key the rig and adjust the Plate capacitor (tune or tank) thru its range for maximum RF voltage. You should then be able to run the NC cap thru its range and see something on the order of a high of 900mv and a low of 10mv to 15mv at the null.

Make sure using a well insulated tool as you are a fraction of an inch from 900vdc anode lead.

If you have 45 volts at Pin 5 and no voltage at SO-239 then you have to have a high resistance connection in the path from the anode to the SO-239 or something shunting this low level signal. I have never seen a bad L7 safety choke. .

I am basing all of this on fact that you report normal full load output and just have plate current dip not occurring at max RF output. A common problem on low bands and of no concern. As long as can get plate current dip and max rf output to occur close to same at 28mhz that is all you need to prevent tubes from taking off on 10 meters. Tube interelectrode capacitive reactance as you move lower in frequency makes it very unlikely tubes will oscillate. Use to neutralize at 21 mhz in attempt to gt it to work across all bands and was not necessary and designers changed procedure to do it on 10 meters where Xc is lowest.

One last thing I may have asked does the main plate choke winding look good with no signs of overheating? I suppose another place that could be shunting low level RF back to HV supply?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Terry,
You are right I is very unusual to have no output reading at all.
Yes I do all the steps you are mentioning. So the only way to find out is to open the rig and check if the neut cap is actually hooked up to something..... more and more I get the idea that is has a cold solderjoint or something like that.
As I have mentioned earlier, I can rotate the cap 360 degrees, but there is no point that gives some meter deflection.......

Only on 80 and 160 meter the is a S9 noise level... I have contacted Ken K4EAA, he mentioned a faulty bandswitch. So I am going to check and clean the switch first, so I can eliminatie that option.....

Wally/PA3BTT

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

After loading to full RF output in CW mode do you just unkey rig and turn off the SG switch and connect RF probe and re-key the rig?

Must be in CW mode and Car Pot Level where it was when you loaded the rig.

You also can try adjusting the Drive control for max ALC indication with SG off.

If you are leaving Car Level Pot where it was to attain full output then it would be very unusual to have no RF voltage at the SO-239 connector unless the neutralizing cap was spot on and then typically will not be able to get a complete voltage null.

To test receive sensitivity with the Marker put the rig on dummy load. You dont want any off air signals at this time for this test

I dont know how you will work with a S9 +10 noise level? Sure hope that is not the norm for your QTH?.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

Hi Terry thanks for the rpely
I have followd both manuals but neither did work...
And I have tried both VTVM and RF probe. Rf probe checked with other (QRP) Trx.
and the 28.5 Mhz plus SG switch turned off.
The strange thing is, that there is NO indication at all of any RF signal when keying the 520S.

no matter what the position of the neutralizing capacitor is.... I am thinking of a loose contact of the capacitor.
We have also tried a monitor rx on the local clubstation. but altough there is no RF indication on the VTVM/rf-probe. And also on the monitor RX there wasn't any indication when adjusting the neut cap.

On the low receive thing.....when RF gain fully open (fully CW)noise is peaking at S9+ 10dB.
The marker signal is noticeable under the noise....(but weaker). I will go and follow the instructions in section 6 for trying to resolve it.....

Altough I am restricted to work on 10/20 meters. the set is working FB. Do receive good reports. 5-9/599
on USB and CW.
As mentioned earlier I do get the idea that someone has been poking around in the PA section. turning the neut cap SHOULD give some kind of indication I guess....
But thanks again for the replay.....

---In TS-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Wally

What instructions are you following? Instruction manual or Service Manual? They are different. Did you load to full load first at 28.5 mhz and then turn off the SG switch?

Are you measuring the rf voltage drop across a dummy load?

What does your RF probe/VTVM read when you flip to Send?

Is it possible your RF probe has a bad diode?

Does your TS520SE receive?

If so, place it next to the TS520S on the bench that you are trying to neutralize and place a short jumper in the TS-520SE SO-239 to serve as an antenna. Key the TS520S and tune for max S meter indication at 28.5mhz on your TS520SE.

Now key again and adjust neutralizing capacitor for lowest S-meter indication and audio. After you reach that point then adjust the the plate tuning and load capacitors for a new maximum S-meter level and touch up neutralizing capacitor again.

Use the same procedure if you have a good RF probe and VTVM.

I use a couple of 100 ohm 1/2 watt resistors soldered to a PL-259. Screw it on the SO-239 and now have good dummy load to connect your RF probe, O-scope, or RF millivolt meter across.

Low receive on couple of bands:

Very briefly you say you can hear the Marker on 160 and 80. A more informative report would be what S-meter indication do you get with the Marker signal?

A fully functional and well aligned 520S should be close to S9 with Drive control peaked at approx 1200 if you have VFO set at 1.9mhz. Will be less at 28.8mhz. perhaps S6 to S7.

If Marker signal levels are down follow the Coil Pack alignment steps in the Instruction Manual Section 6 as a first step to resolve.

Do a good visual on all the cores before you start to id any that are cracked. Cant adjust cracked cores. Must remove them. Some folks apply a drop of lube to top of the former. Make sure use correct alignment tool for the core. Easy to rip a coil off the former due to a core frozen in place. Some report success with applying tip of soldering iron to the core to free it.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <sw20plus@...> wrote:

A couple of month ago I received a TS520 for FREE.. nice of cousre.
The endtubes were a 6146A an a 6146B. So I swapped them with 2 6146B's from my old TS520SE. here it comes.

1. I cannot neutralize thePA. I have connected a VTVM AND a rf probe to the set and followed the manual precisely.. But I have turned the TC1 neutralize cap 260 degrees. but no change in deflection of the connected meters... The set is working FB however. But the deip in Ip is not coniciding with the max RF output. .

2. The set is quite deaf on 1.8 en 3.5 Mhz just a loud hiss... when i use a crystal oscillator in the vicinity I do hear the freq of the xtal though.... but a HAM nearby I cannot hear on 80 meters.... Is that just a matter of re-alignment ?? the rest of the band are receiving FB.
I have attached a end fed halve wave for 20 mtrs. so I can only tx on 20 and 10 meter

Tks

Jim,

I've seen this post several times showing up
here. Surprised no one has responded. What do you mean by ALC overshoot?

Mark

46155. RE: TS520S low receive and no RF output or plate current

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-11-29 14:44:30 UTC
From: <lonelyone_64109@...>
Topic: 45930 Message: 46155

I watched the video and here is an update on the rig:
Checked all voltages on the PA board and the driver board with the SG switch in the on position. I was able to get the PA idling current to register and have it set for 60 mA. The receive is still down as well as no output. While listening on a second receiver (Drake TR-4C) I was able to to hear the output of the 520S as I attempted to tune it up (still no output on the power meter). The signal strength was stronger when I switched from TUNE to CW.

In the receive mode with the calibrator on the S meter is only reading S5 to maybe S7. Some bands are not as good as others as far and in the WWV position WWV is not very strong at all. So maybe a quick check of the coil pack tuning will be in order soon. I broke out the RF generator and plan to do some signal injection in the receiver chain to see if there is anything out of the ordinary.

Here are the voltages I get:

HV: 933V
210 Supply: 256V
300 Supply: 344V
14 Supply: 14 V
-6 Supply: -5.9V

---In ts-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

Paul,

You also might want to watch my video on the 520/820 cathode circuit. The video can be found at the following link:

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/TS520%20and%20TS-820%20Cathode%20circuit%20calculations.wmv http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/TS520%20and%20TS-820%20Cathode%20circuit%20calculations.wmv

My video assumes the cathode resistors are 10 ohms each, not 9 or 11 ohms and the meter multiplier resistor is 3.3K. Actual cathode and meter multiplier resistor values will not be exactly 10 ohms and not be exactly 3.3K.

You can use different values of cathode current, such as 60ma for example, to determine what the cathode voltage will be then use the cathode voltage to determine what the voltage applied to the meter will be. Not all meters have the same exact internal resistance. I used the resistance values indicated in the video to keep the math simple, actual resistance values will be slightly different.

I checked the SG switch and it is on. When I have the radio in the USB or LSB position and speak into the microphone I get a normal ALC deflection with the meter in the ALC position. With the meter in the Ip or RF output position I do not see any movement. Also when I put the rig in the tune position and try to adjust the drive control through its range I do not get any ALC, Ip or RF output indication at all, . The same goes for the 60 mA plate idling current. Thinking it MIGHT be the metering circuit I even put a wattmeter in line with the dummy load but again no power output. I need to go through and check the voltages on the final board, the RF board, and possibly the IF board. I also have a service bulletin reprint saying to check the -6V source as it could also cause low receive and no TX output. But due to my work schedule it will be Thursday evening before I can get any time to further look into this problem. Since there were several resistors burned up i am thinking there is one that I have not found that is open and is causing the lack of RF output and meter indications.

On 11/17/2013 1:13 PM, Mike wrote:

Paul,

You said the ALC meter position works fine. Are you saying that in TUNE mode with the meter switch set to ALC and the transmitter keyed with the SEND switch, adjusting the DRIVE control produces ALC meter indication? You also said there is no 60ma idling current with the transmitter keyed with PTT in LSB or USB, is that correct? If both answers are "yes" then you need to check the rear panel's "SG" switch to ensure it is in the "ON" Position. Quite often when handling the transceiver this switch gets slide, accidentally, into the "OFF" position. When that occurs there will be no 60ma idling current indicated on the meter (meter switch set to IP) when the transmitter is keyed in LSB or USB.

On 11/17/2013 12:42 PM, lonelyone_64109@... mailto:lonelyone_64109@... wrote:

I have a TS520S that the cathode and screen resistors were burned up due to being overdriven.(the owner turned up something when his friends on the air said he was really weak). I've replaced the resistors as well as the 470 ohm resistors in the 210 and 300 volt supplies. I also replaced the caps and RF choke in the final cage as per K4EAA. Prior to installing the tubes I checked the voltages and the HV was 933, the 210 read 256, and the 300 supply read 344 (all were no load values). I installed the tubes and the receive is very low. The S-meter reads S-2 in receive but does drop to zero in transmit. All bands are working as I can hear the phone stations running the sweepstakes this weekend. The crystal calibrator works fine and the signal lever from it is around S-5 to S-9 depending on the band.

I plugged in a microphone and the rig works in VOX as well as PTT and the ALC position on the meter reads fine. I am not showing any plate bias current on the meter when in transmit but but I do have the HV reading on the meter when I switch to transmit.

I am wondering if i missed something that may have gotten burnt or has opened up. With the exception of the receive and no output the radio is working just fine. Any help would be appreciated.

Hi again Guys,

Thanks for all the replies. I removed the counter unit, took the two boards out and inspected the solder joints and the connectors. What was immediately clear is that a prior owner did exactly what you all recommended. It appears that all of the solder joints and particularly the through hole component side ones were re-heated and re-done. Not to take any chances, I went through the process again, re doing each solder joint, (real fun task). Put it all back together, and – no joy. Same problem with no change, (at least I didn't make anything worse)! I guess I'll need to bone up and counter and clock circuits and start some more in depth troubleshooting.

Regards

Tom

Subject: [TS-520_820_530_830] TS-820S Digital Display Problem

Hello to the group,

Long time member, first time poster.

Some background on me. Licensed about 12 years ago, Call is W7OA, name is Tom, and I'm in Reno, NV. I enjoy working on / restoring older radios / amps, mostly from the tube era and have worked on, (and own - much to the XYL's chagrin), a fair number. I have worked on a few hybrids, both Kenwood and Yaesu so not totally out of my depth here - I hope. I would consider I have decent troubleshooting skills and a fairly well equipped bench.

So, on to my problem: A TS-820S I'm bringing back to life is now working fine except for an issue with the dgital display. The display works properly on all bands except the four 10 meter band segments. On these segments the display wanders around apparently randomly, showing around 23. xxx or 24.xxx mhz. The receiver is however receiving on the proper frequency, as checked with a SG. Also oddly, once properly loaded up for transmit, the display shows the proper frequency while transmitting, and reverts to random numbers during receive. This is the case on all four 10 meter segments.

I'm hoping someone in the group has come across this or a similar problem before and can give me a shortcut in the right direction.

Thanks for any help.

W7OA

Tom, Reno, NV

The TS-520 specifications, tuning instructions, microphone impedance requirement, and much more important information can be found in the operator's manual. A lot of questions relating to operating the transceiver, the answers can quite often be found in the operator's manual.

I have discovered (too many times) that the spring wire terminals
inside the white connectors go bad.
They lose their Spring and then no longer make contact with the pins
they are pushed onto. some are actually even snapped into two pieces
when you remove the metal terminal from the connector.
Check those closely !!
I can't tell you how many of those I have repaired on the TS-820 radios.

OK am back home so was able to do some signal injecting on the rig with some puzzling results.

First off I need to replace those pi-filter electrolytics, as with a signal fed to antenna input it drops steadily almost immediately from switch on. If I turn off and leave for a few seconds then the signal is nearly at original level when I turn back on, but starts dropping.

But the really odd thing is that I get an S9+ signal when I inject at the gate of Q5, compared with around S3 when I inject at the anode of D11. The only parts in between are the transformer T5 and coupling cap C40.

Trouble shooting slightly complicated by the lead identifications given in service manual for the Q5 2SK19. It's a TO92 package and the leads shown in manual do not match those on datasheet. In the TS520S manual the diagram of Q5 next to x-ray of rf board on p18 shows gate as centre lead, but datasheet shows source as centre and suggests manual has transposed Source and Gate (Drain positions agree).Has anyone come across this problem or did Kenwood use a different version of Q5 with the ledas shown in their manual? I checked datasheet as the board layout didn't seem to agree with circuit diagram, and I got low signal injecting at what manual said should be gate (centre lead) but which is source according to data sheet.

I get a stronger signal injecting at the drain than I do injecting at gate, by a couple of S-points

So could there be problem with C40, or even the transformer? I wouldn't expect passive non-electrolytic to fail but it's the only interpretation I can see for my readings.

The ALC overshoot on the TS-830 (I think other Kenwood hybrids to this too) is when you have the carrier adjusted to 50 watts for CW, then the first dit is at 130 watts. That is ALC overshoot.

It's really hard on an amplifiers and probably really tears up the band.

Ideas?

Are the filaments actually lit in the tubes? Did the filament lead from the tube socket board get broken off when you replaced the cathode resistors? Do you have plate voltage on the top of the plate choke?

On those 2SK19 lead diagrams, I see the pin out for this device shown on main schematic of service manual agrees with data sheet (source centre pin), and differs from the lead description shown on the same device below the x-ray drawing if RF board earlier in manual. I have scribbled correction note! So I'm left wondering if my problem is with C40 or even T5, and also why the signal strength when I inject at gate of WWV RF amp is a couple of s points lower than injecting at the drain? However when I inject at drain I get same s-meter as if I inject at antenna on ham bands with appropriate frequency at same level, so it does seem my problem just with C40/T5 (but looks difficult to replace either component)

I have a VFO-820 that is causing the digital display on my 820S to sometimes act erractic and sometimes disappear altogether. It happens around a couple of the same tuning spots on the VFO-820. When the display disappears, so does the receive. I can bump the VFO-820 knob and bring it back. The internal VFO and display work perfectly without the VFO-820 so I definitely feel this is an issue with the remote VFO. Ideas, fixes??

My lovely TS-830S has fallen ill. Output is progressively down from 15 - 10 meters (50 watts on 15 down to 7 or 8 on 10).

When I bought the rig -- which was a mess -- I replaced the HV caps, cathode resistors and components in the finals cage among other things and the radio worked perfectly for a year. Today, it went kerflooey. New finals and a new driver have not helped.

Anyway, it could use some REAL expertise. Whaddya think?

Many thanks and 73,

Craig

Jim,

Check the remote VFO's "wiper." You will have to open the case, remove the screws holding the little side window in place(it's easier to do this than the one on the rig). Look to the rear of the
VFO air variable capacitor and you'll see a "brass colored" piece of spring metal at the end of the shaft. Spray some good contact cleaner here...and operate the VFO's knob through it travel
several times...blow out with "canned air" and repeat. This VFO is the same as the one on the 820 and can suffer from the same problem of "crud" at this location. Before you button it all back up, check for proper operation. It's also possible that you may have a loose connection
at one of the sockets or the plugs at either end. Check for continuity of pins 8 & 9 while wiggling the cable.

Craig,

When you adjust the DRIVE control in TUNE mode for a peak ALC indication on 10 meters, start to drop back towards zero (leave the xmtr keyed for a few extra seconds while watching the ALC meter)? If it does then the driver is weak.

The driver tube will show up as weak more so on the higher bands then it will on the lower bands.

Some how I made a changed in my response that didn't come out right.
What I meant to say is:

"When you achieve a peak ALC meter indication in TUNE mode on 10 meters, leave the xmtr keyed for a few extra seconds (won't hurt the xmtr), does the ALC peak indication start to drop back towards zero? If it does then the driver tube is weak and is most likely the source of your problem. A weak driver tube will be more evident on the higher bands such as 15 and 10 meters than on the lower bands."

46174. Poor TS520SE selectivity on CW!

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-01 23:05:04 UTC
From: <adrian@...>
Topic: 46174 Message: 46174

I seem to have had a one step forward, 2 steps back day while troubleshooting a WWV sensitivity issue on my TS520SE.

After doing work with signal generator, I found receiver was behaving bizarrely on CW. Seemed to be no selectivity with injected signal - could hear tone and get high s-reading moving dial + or - 50 kHz from injected frequency on say 14 MHz.

If I just used the rig's 25kHz marker, then this meant I was hearing pretty much continuous tone no matter where main tune dial was, and s-meter was always around S9.

Everything is normal on USB and LSB, and I have also found that the selectivity problem does not exist with the "wide" position selected on CW filter switch, but only when switch is set to "narrow".

Am sure this was not a problem before I was poking around today, so I'm wondering where to look for fault I may have caused. The symptoms suggest CW filter is problem but hard to think how it could have been damaged when I was simply injecting signals on RF board. I have checked that the brown wire to CW terminal is in position too, so the filter is being switched in when "narrow" selected.

Any ideas please?

46177. Kenwood Net Update (December 1, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-02 02:44:07 UTC
From: Mark Gilger
Topic: 46177 Message: 46177

The Saturday net on 40 meters had 18 check ins
under good band condition. There were 3 new check
ins, K4CEG, VE3RBX, and WB3JQO. We had the
following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
2 running TS-830S

I was using my TS-940s.

The Sunday□s 20 meter net had 16 stations
checking in under good band conditions. We had 6
stations checking in from California. There were
5 new stations checking in, KG7FWG, KJ4AZA, K6WGY, KC2AYB, N7QZ, and N4JK.

Out of those, there was:

4 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
6 running TS-830S

The rest were running non hybrid equipment. I was running my TS-940S.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54
October 2013, Saturday☐s net total = 61, Sunday☐s total = 55
November 2013, Saturday☐s net total = 94, Sunday☐s total = 85 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Jim,

I approved your membership on 11-27-13, since then you have attempted to post
 8 messages...but only 6 seem to have appeared in the record. I have personally
approved your posts to be sent to the groups main message area. As explained earlier,
new members, regardless of who they are, have their posts/messages "moderated" at
first. You may have something wrong with your ISP or browser....I don't know. I have seen
all of your posts with the exception of 2 that were sent by you on 11-29...according to the
record..you sent 4 on that date. What happened to the other two??...don't know.

If there is any doubt...go to the "main" or "home page" of this group, click on
"conversations"
it is on the far left middle of the screen...under the picture...search through and you
will find
that they were indeed "approved" and posted."

I myself have had messages/posts disappear into the "yahoo void" only to appear days later.

Topic: 46167 Message: 46180

Thanks, Mike.

Actually, the symptoms have gotten worse. Drive on 10 meters is now intermittent -- mostly non-existent -- and output power on all bands above 40 is dropping off. The output is wavering slightly, too., seemingly indicating a weakening component or a bad connection somewhere. I suppose it could be the old band switch problem. I cleaned it several months ago when I first got the radio. (The radio had been almost completely inoperative). Others have noted that band switch cleaning is a temporary solution and that bridging the rivets and contacts with conductive paint or soldered wires is the only way to permanently cure the band switch misbehavior.

The driver tube should be okay. I replaced it with a new 12BY7 and there was no change in the problem. The finals were changed, too. Oh, and I replaced the electrolytics on the rectifier board, too.

What about the electrolytics on the IF board? What happens if they go sour?

46183. Driver Tube, Keyer, and Tuner question

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-02 03:26:37 UTC
From: <jason.bogstie@...>
Topic: 46183 Message: 46183

Hey Everyone!

I have three quick questions for you, these are regarding a Kenwood TS-520:

1. If I just replace the driver tube and NOT the finals, do I need to perform the neutralizing procedure from the manual? Is there some procedure for the driver tube that I need to be aware of?

2. Do I need to have a morse keyer to fine tune the radio in CW mode or can I just use the send/rec switch? I am aware I don't need to tune the radio in CW necessarily, but the manual recommends it and I'd like to do it.

3. Can I use the AT-230, as a tuner, to tune a mismatched antenna? Do I have anything to worry about since the TS-520 has a pi network? I am worried about tuning the radio, then using the AT-230 and tuning for the antenna mismatch, and then essentially detuning the kenwood in the process. I am now in a rental house and I was specifically told I cannot mount an antenna to anything or have anything really visible hanging around, so I was thinking about throwing up a random wire into the tree next to my window and tuning it with the AT-230. Last time I tried to tune my Kenwood with the AT-230, I blew a whole pack of fuses, so I just wanted to check.

I appreciate your guys' help!

73,

Jason - K7BOG

From: William Houghton
Topic: 46183 Message: 46184

Jason,

1) I'm not sure. It is not uncommon for the driver tube to be in the neutralization path. I'm sure someone with more experience with the hybrids can chime in.

2) No, you don't need a keyer or a code key. In TUNE mode the keying circuit is activated. "... I am aware I don't need to tune the radio in CW necessarily..."

If you follow the instructions in the manual for transmitting in CW, it tells you to tune the radio with the MODE switch in TUN. It also tells you that after switching the MODE to CW, adjust the PLATE and LOAD controls. This is retuning the final amp stage. This should not be considered optional.

3) In general, yes you can use an external tuner. One of the first pieces of gear you should have is a dummy load. If you don't have one, buy or build one. Connect the dummy load to DUMMY connector on the back of the AT-230. Set the switch to the DUM position on the THROUGH side of the ANTENNA switch. This will connect the dummy load to the rig bypassing all the AT-230 tuning circuits.
Tune the rig into this dummy load. Once you have retuned at full power, leave the tuning of the rig alone. What you have now done is tuned the rig to a known 50 ohm load.

Switch the ANTENNA switch to the antenna you will use and follow the instructions in the AT-230 manual. When the manual says to use a minimum of power, they mean pretty low power, just enough to move the meter needle.

here's what is going on.... your tuner has an input side and an output side. The idea is to adjust the input side so that the input impedance of the tuner matches the output impedance of the rig. Then you adjust the output side of the tuner to match the impedance of your antenna. Since the TS-520 has a pi-network we adjust it to a known value which is why you first tune the rig into a 50-ohm dummy load.

73,

Bill

1. If I just replace the driver tube and NOT the finals, do I need to perform the neutralizing procedure from the manual? Is there some procedure for the driver tube that I need to be aware of?

2. Do I need to have a morse keyer to fine tune the radio in CW mode or can I just use the send/rec switch? I am aware I don't need to tune the radio in CW necessarily, but the manual recommends it and I'd like to do it.

3. Can I use the AT-230, as a tuner, to tune a mismatched antenna? Do I have anything to worry about since the TS-520 has a pi network? I am worried about tuning the radio, then using the AT-230 and tuning for the antenna mismatch, and then essentially detuning the kenwood in the process. I am now in a rental house and I was specifically told I cannot mount an antenna to anything or have anything really visible hanging around, so I was thinking about throwing up a random wire into the tree next to my window and tuning it with the AT-230. Last time I tried to tune my Kenwood with the AT-230, I blew a whole pack of fuses, so I just wanted to check.

I appreciate your guys' help!

73,

Jason - K7BOG

From: Mike
Topic: 46183 Message: 46185

Jason,

Question "1", answer is "No", you do not have to neutralize the final if you only replace the driver tube.

Question "2" (part 1), answer is "No", you do not need a CW key plugged into the rear panel CW key socket in CW mode to produce RF output, in CW mode and flipping the SEND switch "UP". The CW key socket is a "N.C." (Normally Closed) socket.

Question "2" (part 2), answer is "Yes", you need to use CW mode during the transmitter tune up procedure as the manual states. As stated in "Part 1", you do not need a CW key during the "CW Mode" transmitter tune up procedure.

Question "3" (Part 1), answer is "Yes, you can use the AT-230 with the TS-520. However, the TS-520's PI Network cannot and will not tune a "long wire" antenna, you must use a tuner such as an AT-230 between the TS-520 and the "Long wire" antenna. There are other tuners that will also work for long wire antennas. If you do not have a 50 ohm dummy load then I recommend you purchase one and use it when tuning the TS-520 transmitter.

MFJ sells a couple of nice 50 ohm dry dummy loads. You can use a wet (oil based) dummy load but those can be messy. MFJ sells a wet 1.5K dummy load for $69.95 comes with a gal of oil. I never cared for wet dummy loads, didn't like the mess. A couple of dry 50 ohm dummy loads sold by MFJ are as follows:

1. MFJ-260C 300 watts $39.95
2. MFJ-264 1500 watts $74.95

The MFJ-260C has a power limitation you need to observe. The MFJ-260C will accept a constant carrier at 300 watts for only "30 seconds" followed by a "2 minute" cool down period. Based on the graph included in the MFJ-260C manual, the MFJ-260C will accept a constant 100 watt carrier for "1.5 minutes" followed by a "2 minute" cool down period. You must adhere to these power rating specifications otherwise you can permanently damage the dummy load.

You should use a 50 ohm dummy load that has a power rating equal to or higher than the TS-520's 100 watt output and tune the TS-520's transmitter into the dummy load (I recommend a dummy load with at least twice the power rating of the TS-520's 100 watt output).

Once the TS-520 has been tuned properly into the 50 ohm dummy load, by following the TS-520's operator's manual tune up procedures, connect the

TS-520 to the AT-230, reduce the TS-520's power output to approximately 25 watts (CW Mode) using the CAR control and begin adjusting the AT-230 for lowest SWR. Once a low SWR has been achieved, unkey the transmitter to allow the TS-520 final amplifier tubes to cool down a minute or so. Key the TS-520 and increase power output using the CAR control to approximately 50 watts and repeat the AT-230 adjustments for lowest SWR then unkey the TS-520 so the final amplifier can cool down. Repeat this procedure until the AT-230 has achieve the lowest SWR possible. During the AT-230 adjustments, do NOT touch/re-adjust the TS-520's DRIVE, PLATE, and LOAD controls. The only TS-520 control you should adjust during the AT-230 adjustments for lowest SWR is the CAR control to reduce/increase power output to the AT-230 tuner. Depending on the length of wire you use for the antenna, it's possible you will never achieve a low SWR. Wire antennas need to be long. A short wire say approximately 20 feet may not be suitable length for the AT-230 to achieve a low SWR. Again, a "good ground" is a "MUST".

Question "3" (Part 2), You should read the AT-230 manual, page 9, and follow the instructions for "wire antenna" installations. A "good ground" is essential when using the AT-230 with wire antennas. If you do not have the AT-230 operator's manual then I recommend downloading it from the web and read it thoroughly before you attempt to use the AT-230 with a long wire antenna.

Craig,

Have you read the "Survial Guide" document found on the Group's homepage in the "Files" section? That document discusses various problems with the TS-830 and suggestions you should consider. I recommend you read that document. Also, search through the message archieves, Terry K9TW, has provided some excellent information in previous posts that you should look for.

No, I do not believe a capacitor on the IF board is the source of your problem. You should never replace any component(s) or vacuum tube unless there is clear evidence through proper troubleshooting that points to a component or vacuum tube as the source of your problem. Visual inspections are part of the troubleshooting process. Visual inspections quite often uncover overheated/damaged resistors, final amplifier RF choke (discolored windings), and melted wiring. Loss of transmit RF requires tracing the transmit signals (read the 830's Circuit Description section in the operator/service manuals) through the 830. You will need basic test equipment, scope, frequency counter, etc, to perform these steps.

Topic: 46167 Message: 46187

True enough, Mike. And thanks again.

I did replace the driver tube and finals since both were "usual suspects" for power dropoff on the higher frequencies. Of course, the effect in my case was nil.

The topic of electrolytic cap replacement is an interesting one encompassing two distinct schools of thought:

1) the "if it ain't broke, don't fix it" approach, and,
2) the "get it before it gets you", prophylactic philosophy.

A common bit of advice, here and elsewhere, is to replace the HV caps as a matter of routine. One Kenwood hybrid specialist advised me to swap out the 'lytics on the rectifier board and the four 22 uF caps on the IF board, too, "as an absolutely necessary step." Another hybrid service specialist favors replacing every electrolytic in the radio, pointing to the caps' age and an exhaustive analysis of the devices' life cycles in support of his thesis. His argument is compelling, I must say.

Others advise to "leave well enough alone" and, like you, Mike, favor replacing components only if there is clear evidence of failure or deterioration since the dangers of "collateral damage" to sensitive circuit boards and other components outweigh the benefits of a "shotgun" repair operation.

Both points of view have merit.

I routinely restore antique radios and boatanchors and, unless the radio is known to be working perfectly at the outset, begin (after a thorough cleaning) by replacing every electrolytic and paper cap in the chassis, then measure resistors and replace them as necessary. Of course, this is much easier to do and less threatening in a radio with point to point wiring. A circuit board based rig with -- in the case of one of our hybrids -- upwards of a hundred electrolytics alone is another matter.

I am curious about others' opinions on this matter.

Thanks and 73,

Craig

Hello everybody
Hope you all had a nice Thanks giving.
Now I have a Q, trying to help a friend with his TS 520s, the audio board was fried, so got a new one, and put it in, now the receiver comes to life, but no sound, till I adjust the 3.3V on the AVR board up to about 6V.....
The 9V is correct, 14V is also there, but as soon as I adjust the voltage lower, the S-meter goes up, and it sounds like you turn up the RF gain, only very strong signal goes through, also, when I turn up to about 6V, so receiver "works" it sounds like its self oscillating if I turn up the drive max......
Only thing I know about the radio, is that it had a 11m mod, so it does not work on 28.0 Mhz, but all other bands seems ok....
Any ideas?

First a brief rant - is it just me or is the new format for this group appallingly difficult to use? Doesn't even format correctly on my iPhone/iPad if I want to post/reply via web. Very hard to follow threads and generally fights the user.

Anyway here's a cautionary tale. I had been doing some troubleshooting on my TS520SE, and when testing it on receive was getting terrible "birdies" on 80m and topband. Weird noises like woodpeckers in the rig, and s-meter pegging whistles as you tuned through band. Crackles and pops like crazy.

Was trying to figure out source of problem when I realised that I hadn't replaced one of the metal shields on the RF coil board. It was the one between ANT and MIX coils. I had removed it to make room to desolder a component on the RF board. As soon as I popped the shield back in (held by 2 Philips screws) all was restored to normal on those bands!

Hi Dave

That's a good tip but I send replies via the web interface, as I have a different email registered for this group than the one on my mobile devices. I can't just reply direct from email.

The new web interface is the problem. Used to be very fast and reliable. Now it will often refuse to expand posts, not let me click into a reply box, and when I do type characters not accepted! I have a feeling that the lower level of group activity recently reflects problems people are having using the interface.

If it persists I may have to re-register using address letting me use list via email.

I have a back-up TS-520SE that I bought about 2 years ago to use in case my favorite 520SE got sick. The back-up would receive but I never got around to running a full "systems check" on it until this past week. Well, everything checked out okay with the exception that relay RL2 would hang and the Band selector was a bear to try and turn. A little contact cleaner took care of the relay problem but why, oh why, was the Band selector being so difficult?
The previous owner must have had the same problem with the Band selector because he took the time and effort to apply liberal amounts of black grease to the selector shaft just behind the face plate. Of course this black goo was of no help and I carefully removed all traces of it.
The tuning shaft appeared straight and there was no evidence of any physical damage but why, oh why, was it so difficult to turn? I have arthritis enough to make me sometime wish that my thumbs would fall off and running the Band selector through its full cycle in its current condition was not a pleasant experience.
I could kick myself, again. While listening to a little chatter on 20 meters it struck me. The solution was right there, staring me in the face all the time. Some previous owner had switched the knobs! He had put the Function knob on the Band selector shaft and the Band selector knob on the Function shaft. Problem identified; problem solved.
Ah, it's not easy being me sometime.
There's no need for a response to this posting. I only wrote it to make people smile a little, nothing more.

Hi Charlie,
I'm new here but I enjoyed your story so I thought I would comment.
It's a good incident to remember however. Also a credit to your smarts to deduce the solution.
I wont forget that as I'm refurbishing Kenwoods' and all the knobs come off so I can remove the faceplate and scrub everything. It's fun I'll tell ya.I think alot of hams like to eat their fried chicken while they ragchew.
I could see myself making that mistake with the knobs.

Maybe even getting out the grease gun.

Not really.
Thanks for sharing.
Michael///KD0WSJ

Subject: [TS-520_820_530_830] A humorous TS-520SE story before Christmas.

I have a back-up TS-520SE that I bought about 2 years ago to use in case my favorite 520SE got sick. The back-up would receive but I never got around to running a full "systems check" on it until this past week. Well, everything checked out okay with the exception that relay RL2 would hang and the Band selector was a bear to try and turn. A little contact cleaner took care of the relay problem but why, oh why, was the Band selector being so difficult?

The previous owner must have had the same problem with the Band selector because he took the time and effort to apply liberal amounts of black grease to the selector shaft just behind the face plate. Of course this black goo was of no help and I carefully removed all traces of it.

The tuning shaft appeared straight and there was no evidence of any physical damage but why, oh why, was it so difficult to turn? I have arthritis enough to make me sometime wish that my thumbs would fall off and running the Band selector through its full cycle in its current condition was not a pleasant experience.

I could kick myself, again. While listening to a little chatter on 20 meters it struck me. The solution was right there, staring me in the face all the time. Some previous owner had switched the knobs! He had put the Function knob on the Band selector shaft and the Band selector knob on the Function shaft. Problem identified; problem solved.

Ah, it's not easy being me sometime.

There's no need for a response to this posting. I only wrote it to make people smile a little, nothing more.

73
Charlie

Topic: 46204 Message: 46204

Hello All,
After a few months down I am back at the bench with a real stickler.I remember some discussion about this a month or 2 ago but it did not mimmic my particular problem so I need some help. I have beat this problem up and thought it led to a faulty Q18 but after replacement, no joy. This is where I am now. Replaced AV board with new board and rechecked voltages. Still have the following: at Q18 Base= -7.4 v,
Collector= -5.78 v, Emitter= +.5 v. Have stable -115 v at -C post. I cannot find my problem area. I started thinking every whacky thought but figured I needed help. I did inject -6 v on IF board connector 3 pin 1 and receive is good. This rig was a basket case from Ebay but everything is now working except this AV problem. Rig loads on all bands into dummy load but have to supply outside -6 v to receive. This is the first time I have had a receive problem so I do not have experience with the AV section. What say the group?
Thanks in advance, Don K5HFG

Topic: 46208 Message: 46208

Any suggestions for the following problem much appreciated: Replaced the cathode and screen resistors including on the rectifier board, rewound RF choke to repair broken copper enameled wire, glued to the ceramic post with clear nail polish and resoldered to the parisitic resistor post, replaced the plate coupling capacitor and turned on the rig to check results. Rig display shows 500 kc below the band switch position, e.g., at 10 mhz shows 9500, at 28 shows 27500. NO sound or signal. Picking up and dropping the rig causes display to return to normal and signal returns but staticky. Shortly reverts to the same problem. Checked for cold solder joint, loose connectors etc but no luck. Rig was working normally but with moderately low output prior to repairs. Any thoughts please!
Thanks, Joe - N5XJT

46209. TS-820 VFO problem

Topic: 46209 Message: 46209

Hello to all new to this group. I own and I am the original owner of a TS-520S. However my question is about a friends TS-820. He just recently moved and when he fired up his 820 it had VFO problems. It doesn't track as you turn the knob. It goes for example from 3.599.9 to 3.715.5 not 3.600.0 and it may even go backwards when it should be going foreward. Any help would be great. Would like to get it back on the air for him.

Thanks

Tom N8NMA

Gordon,
Thanks for pointing me back to the counter board. All was fine with the counter so after that it was a no brainer. All I needed was a gentle push away from what I thought just had to be the source of the problem. So, if we got -6 at the counter board but no place else it has to be a broken line. Found it was detached from the notch filter PB switch after a brief consult with the schematic. had to be that. repaired and back to 100%. I cannot believe I spent all that time in the wrong place. It will take an hour or 2 to rebundle all the wires but at least it is fixed. Thanks again and 73. Don K5HFG

Joe,

Does this radio have 11 modification? When on 28, and moving VFO past the 28.000 mark you should only see 27.924 (approx) as lowest freq. Have a look on the PLL board connector 2 to see if purple (from memory) has been cut or is broken. All the other work you have done shouldn't create problems with the VFO\display

I'm new to the group. Just back in Ham radio after 42 years...
Been studying the Kenwoods'. My first thought on your problem is your bandswitch isn't working real well. "Old and Dirty", like me.
(although I'm older and dirtier)
Especially if jarring the radio helps it or changes what it's doing.
If you use deoxit on the wafers wait until you are sure it's dry before using rig.
Poor guy on eBay bought a nice TS-830S and cleaned it and Deoxit caught fire.
I've bought alot of his parts.....missed out on the RF board, dangit.
You could also use "mass air flow sensor" spray cleaner after Deoxit.
MAFS is a zero residue cleaner, easy on plastics. Less likely to have a fire and destroy your radio, it'll cost you about $8 at auto parts store.
Try some deoxit on your wafers. Be sure to get the 3 or 4 in the HV cage too. Wait long enough for it to dry. Will definately help.

Thanks for those links Mark. I think I have N6WK already but that other one is a valuable wealth by the looks of it. (it would help if my crap computer and my small internet bandwidth downloaded better).
I concur on the vfo fix, prolly the mechanical elec connections inside the box.
I've got an 820S on the bench right now, RF board is out to detail the wafers and VFO cover is off. Much easier to work on both with it out.
Had to get ready for storm, put up 3 cord of wood. Now with bad weather I can feed the woodburner and work on my radios.
It's a pretty easy fix for most of the VFO problems Tom, you can handle it.

You said you performed the start up procedures and everything went well except the meter remained at zero when you pressed the microphone's PTT button. The TS-520SE does not have a HEATER switch, the filament power is applied any time the ON/OFF main power switch is in the ON position.

Did you check the SG switch on the back of the transceiver? It should be set to the "ON" position. Quite often handling/moving the transceiver can result in your hand/fingers accidentally moving the SG switch to the OFF position. If you don't know where the SG switch is, refer to the 520SE operator's manual, pages 12 and 18.

Also, did you check the rear panel's External VFO socket? Either the factory 9 pin plug or a jumper wire connected between pins 8 and 9 is required. If the plug or jumper wire is missing then the internal VFO will not receive it's 9VDC operating voltage. This will result in the 520SE not working in receive and transmit. Note, the rear panel External VFO factory plug or jumper wire has nothing to do the meter's IP 60ma idling current indication (Mode switch set to USB or LSB) with the microphone's PTT button pressed or the SEND switch flipped "UP" (keys the transmitter). If you don't know where the 520SE's rear External VFO socket is then refer to page 7 and 12 in the 520SE's manual.

I also noticed you did not end your message with your name and/or ham call sign (signature). You must end all of your messages posted on the group with a signature which can be either your first name and/or your ham call sign. "Screen names" such as hd13777 are not acceptable signature names. Screen names are only acceptable as part of your email address, not as a signature to your messages. Therefore, ensure all future messages you post on the group have a signature that is either your first name and/or your ham call sign.

I hope I'm not treading on any toes with mine. I'm probably more widely known by my old BBS nick that I've had for the thick end of 30 years than my real name - which is of course readily discernable from the call book or online listing of your choice.

No, it has not been modified. Normal VFO operation shows about 27.920 as lowest. I agree the repairs should not have impacted but the problem did not show up until after.
tks,
joe - nfxjt

This was my first thought too but the band switch changes correctly, and was working fine prior to repairs. Normally a dirty or faulty band switch will only cause problem on certain band or bands. Also, it was cleaned about 12 mos. ago by a very good tech (AVVID). Dont think a dirty band switch would cause the default to drop. No matter what band I select the display shows 500 kc below the band and internal or external Vfo will not change the display. Frustrating!

> Â
> Any suggestions for the following problem much appreciated: Replaced the cathode and screen resistors including on the rectifier board, rewound RF choke to repair broken copper enameled wire, glued to the ceramic post with clear nail polish and resoldered to the parisitic resistor post, replaced the plate coupling capacitor and turned on the rig to check results. Rig display shows 500 kc below the band switch position, e.g., at 10 mhz shows 9500, at 28 shows 27500. NO sound or signal. Picking up and dropping the rig causes display to return to normal and signal returns but staticky. Shortly reverts to the same problem. Checked for cold solder joint, loose connectors etc but no luck. Rig was working normally but with moderately low output prior to repairs. Any thoughts please!

Gordon (MM0YEQ),

You use your call sign as a signature which is acceptable. There are some members who do not use a signature or their signature contains an unacceptable "screen name" as the signature. Joe has sent a couple of reminder messages out to everyone about the signature requirement. It's the responsibility of ALL members to read, understand, and adhere to the signature rule.

Also, every "new" applicant for group membership is sent a "Welcome" message. The Welcome message clearly states the message signature requirement. It's the responsibility of ALL new members to read the Welcome message and adhere to the message signature requirement, it's that simple.

Jim,

What do you mean when you say there is "no output"? No "RF output, No audio output? You need to explain in more detail what steps you took to come to the conclusion there is "no output" and what you mean by "No output"

I have a TS 820S that has slightly low power output. I have already checked the tubes and other such basic stuff including screen voltage, etc.

I always saw about 900V no load on the HV on previously owned 830's but I am seeing only 800V no-load on this 820....

Can anyone tell me if this is a "red-herring" or if my HV is low with no load?

I already installed new HV caps/resistors....

Thanks,

Greg

Greg,

Are you using the 820's "HV" meter indication to determine whether the HV is low? If you suspect the HV is low, you should measure the HV at the TS-820 Rectifier Unit's 800 terminal. Use caution because the HV is present on the plates of the final tubes and at the Rectifier Unit's 800 terminal regardless whether the TS-820 is in receive or transmit. None of the TS-820 meter switch settings are enabled in receive.

If you are reluctant to measure HV then I recommend you find a local ham who is experienced in measuring high voltage. The DC volt meter should have a maximum DC voltage rating of at least 1KV. Do not attempt to measure the HV if your DC meter has a maximum DC voltage rating of 700VDC.

I still see members that are not adding a signature at the end of their messages. All members are required to include a signature at the end of any message they post on this group! The signature can be either your first name, your ham call sign, or both. Screen names are not acceptable names used as signatures!

Well it might be the 10 MHz crystal is off frequency. When I first got my 530 it would read 400 hz. lower than where I wanted to be. Turned out the 10 MHz crystal had changed. Got a new crystal and reset it and everything was fine after that. There is a test point on the PLL board to check and adjust this. it is step 6 on page 36 of the alignment instructions. You will need a frequency counter on TP2 and adjust TC1.You will find these test points on page 44 of the service manual.
Also I might mention, is the RIT and XIT buttons out as this is the off position. The RIT can change the rec freq. and the XIT will change the transmit freq. Those adjustments are on page 34 step 5.
Let me know how you make out. Compared to my 830 the 530 is much easier to repair. The 830 is a little more complex.

Hello Joe,
I have not been able to get a post in here till now but I have been following your problem and yhe several responses. I do not think it is a bandswitch problem. Dave, VK5PDL, is on the correct track. I have a 830 here with the same problem. I had to put a new molex connector on connector no. 2 on the counter board. It seems, and I was not aware of this until Joe and a few others clued me in, that some unscrupulous radio operators institute a mod known as free banding. The purple wire is removed on connector 2 pin no.9 and viola! you got the high end of 11 meters. exactly 500 Kc's down from 28 Mc's. On my 830 the wire was just pulled out willy nilly and left hanging. I put it back in the connector but soon began to experience the same symptoms you describe. Do not bang your rig around to check for this connection being loose in the socket. Use a plastic slug adjustment tool and move the wires around and see if it results in the problem reappearing. If the wires inside the connectors are showing age or brittle or corroded this intermittent problem can be one of many to show up. Keep us updated on your findings. This may not be your problem but I thought I would give you the benefit of knowing it could be. Check this first before doing any major teardown. I do not think you will have to go that far. You may want to find some spare molex connectors to keep in your parts box or bench. They will become one of many parts you may need to keep this fine rig going. If I have misspoke on any of this detail someone will correct me but I think your problem is an easy fix.
73, Don K5HFG

Topic: 46238 Message: 46238

Hi All,

I just got a nice 100W dummy load kit off ebay. It is a project of the Muskegon Area Amateur Radio council, W8ZHO. Comes with 20 resistors and fittings and a quart paint can. Also some test ratings. In the oil filled can this dummy load will take a 2 minute key down at 100W, conservatively.

The price was $14.95 plus $4 shipping or you can make an offer. If you want one completely assembled, it is $5 more. Lazy me got the assembled version and it was well soldered. One bolt needed a little tightening, o/w very well done.

I thought it was a good price on a useful unit for a good cause. You will have to get your own mineral oil. I am using some out of a gallon of horse laxative I got from Tractor Supply to use in my rock saw, which goes for about $12/gal.

There seem to be about ten or more of these available. use "dummy loads MAARC" to search for the listing.

HTH,
Roy Kersey

I wonder if they ship to the UK?

Many years ago I'm sure I remember my dad filling an oil-immersed dummy load with automotive hydraulic fluid (LHM) left over from changing the suspension oil on his Citro?n GSA. It's a bit thinner than ATF and bright green with a slightly sweet smell, and not particularly inclined to be inflammable.

Having just changed the hydraulic oil in my CX these days I'd be inclined to use something much cheaper, like 18-year-old single malt.

The website for W8ZHO's 100 watt wet dummy load appears to be "under construction". The "cached" link, however, indicates W8ZHO's 100 watt wet dummy load is priced at "$25" and there's no indication the dummy load comes as a "kit".

I don't mean to sound disrespectful but something doesn't seem right.

Lets look at a few dummy loads, focusing ONLY on each manufacturer's statement of where each dummy load can "safely" accept "full rated power" for a specific period of time. We are NOT concerned with the difference between 1KW and 100 watts, only the "period of time" the wet dummy load can 'safely" accept "full rated power", nothing more!

Heathkit and MFJ both state that their wet dummy loads, when filled with Mineral Oil, can "safely" accept "full rated power" for only "10 minutes".

W8ZHO states his wet dummy load, when filled with Mineral Oil, can accept "full rated power" for an "indefinite" period of time.

If Heathkit and MFJ test results state their wet dummy loads can "safely" accept "full rated power" for 10 minutes, what makes W8ZHO's wet dummy load be capable of "safely" handling "full rated power" for an "indefinite" period of time? Again, focus on the "period of time" the dummy loads can "safely" accept "full rated power".

It's entirely up to you as to the type (wet or dry) and power rated dummy load you use. Personally, I would not use any 50 ohm dummy load, wet or dry, that has a power rating that's less than 300 watt when used with an exciter that has a power output rating of 100 watts.

Don't take its readings as gospel. It's not particularly calibrated, and is more of a go/no-go indicator.

I wouldn't expect 800V to make much of a difference - maybe you'd see 80-90W instead of 100W output. The variation between individual radios is more than that, and it won't affect how well others hear you.

I bought my kit from Ken K4EAA and it was easy to build. I think Ken said 120w for 5 minutes and a 20 minute cool down. I could be wrong on that, but I have dumped 150 watts into it for a short time and it still reads 49.8 ohms and it is over a year old. Great little dummy.

For a (usually) free source of oil for these paint can dummy loads, try the local power company. When I lived in Las Vegas many years ago I got a gallon of transformer oil (the kind without PCBs) from Nevada Power for free. Just ask for one of the technicians & they will probably be glad to give you some.

All fixed - the WWV RF amp FET Q5 was blown. Replaced with another 2SK19GR and can now copy the time signal. S-meter with marker signal on that band is now way over 9. Really pleased to have rig back on air - plugged antenna in to test and first QSO was on a still working 15m band with a station in Minnesota

Don,
Thank you for your reply, it is much appreciated. Fortunately my rig has not been modified. I did however locate the problem using your suggestion and moving all the wires/connections around with a plastic alignment wand. Took about 20 min. but I found it. In laymans terms it was the long gray wire on the PLL board, X-50. Wiggling it restores correct frequency read out and signal reception. Fix is in progress.
Thanks for your help,
Joe - N5XJT

>
> Hello Joe,
> I have not been able to get a post in here till now but I have been following your problem and yhe several responses. I do not think it is a bandswitch problem. Dave, VK5PDL, is on the correct track. I have a 830 here with the same problem. I had to put a new molex connector on connector no. 2 on the counter board. It seems, and I was not aware of this until Joe and a few others clued me in, that some unscrupulous radio operators institute a mod known as free banding. The purple wire is removed on connector 2 pin no.9 and viola! you got the high end of 11 meters. exactly 500 Kc's down from 28 Mc's. On my 830 the wire was just pulled out willy nilly and left hanging. I put it back in the connector but soon began to experience the same symptoms you describe. Do not bang your rig around to check for this connection being loose in the socket. Use a plastic slug adjustment tool and move the wires around and see if it results in the problem reappearing. If the wires inside the connectors are showing age or brittle or corroded this intermittent problem can be one of many to show up. Keep us updated on your findings. This may not be your problem but I thought I would give you the benefit of knowing it could be. Check this first before doing any major teardown. I do not think you will have to go that far. You may want to find some spare molex connectors to keep in your parts box or bench. They will become one of many parts you may need to keep this fine rig going. If I have misspoke on any of this detail someone will correct me but I think your problem is an easy fix.

I know this doesn't pertain to Kenwood rigs, but it is important.
We lost another Ham Radio Operator this morning about 8:30 am EST. I stopped by this morning to see if he was ok and I found him in his chair where he slept most of the time. He was cold and no pulse. I called 911 and got the police and ambulance there. They called the coroner, His name was David Kuenzel. WB8TMR. He was my Elmer and got me started into ham radio 35 years ago. He fought Prostate cancer for 6 years. In fact He gave me my first TS-530s which I still have. I talked to his niece and Dave wanted me to have his radios and antennas. I will take them an use the well in memory of Dave.

Topic: 46238 Message: 46255

Mike:

IDK about any website or whether it is selling the same kit. If you investigate the ebay listing, which was what I wrote about, there is a picture of part of the instructions which come with the kit, describing a test on the dummy load without oil filling. The dummy was loaded up and the resistor temperature checked after each 15 seconds of power application. The resistors tolerated about two minutes of key down at 100 watts. This is without the oil filling. Obviously with oil filling it would work fine for longer than two minutes.

I don't really have a dog in this fight and anyone can buy it or not as they see fit. It just seemed like a reasonable price to benefit a ham organization and a decent product which would work with one of the 100 watt (nominal) Kenwoods if used in any reasonable fashion. I myself would not hold down the key to wait to see whether my dummy load would explode .. .

Best,
Roy Kersey

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

From: <adrian@...>
Topic: 46261 Message: 46261

I guess I'm proving the adage that if you fix one thing on these rigs, you risk introducing problems elsewhere!

Have had my TS520SE on bench to replace the WWV RF amp FET which had blown. RX working perfectly now on WWV and is fine on all other bands all modes.

But now the transmit side has gone weird. It was fine before with 100W or so on all bands and a bit less on 10m and Ip 200mA.

Here are the symptoms I'm seeing. They are so erratic that methodical troubleshooting will be difficult so I'm hoping someone spots something simple I can check.

First off idle current is adjusted to 60mA.

The ALC seems much "livelier" than before when I am in June position and peaking it. Before I had to wind carrier up to full to get full scale ALC on 10m, now only need carrier halfway on that band and on lower bands I get full scale FSD with lower carrier drive than before (around the indicated 3 position).

Having peaked ALC with Drive, I can't get the plate to dip. When I switch to CW I see over 200W on external RF meter when I peak load and the plate current is only about 120mA. Something very weird going on so grateful for where to look!

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

Hi Folks,

I am a new member of this group having just purchased a TS 830s transceiver.

The radio is working well on receive on all bands and after studying videos
and reading
Lots of instruction on the tuning procedure, I am preparing myself to take
the plunge and
Make an attempt at tuning it up.

My question to the group is as follows.

Will this dummy load be suitable for the tuning up process?

Toyo Meter wide band dummy load, model T-100.
3.5 MHz - 500MHz. Impedance 50ohm.
Maximum power 100w.

My thanks in advance.

I'll be honest and admit that I start with uneducated geusses.
My first? Check tubes.
You just had that RF board out, check wiring plugs to that board. Did you take the time to brush and coat those plug pins while the board was out?
I have learned that I can use little stainless brushes lightly sprayed with Deoxit to brush and REALLY clean those pins. I feel safer about doing it with the boards out of the radio. Occasionaly the brushes will drop a wire, you darn sure don't want those floating around inside your radio.
Those dang plugs are the most common problems in the TS radios.
Pull a board, clean them.
I'm now using CorrosionX applied with an artists' small brush. The 2 bottles I bought should last me 372 years...
Hope that helps,
Michael///KD0WSJ

Subject: [TS-520_820_530_830] TX problem on TS520SE

I guess I'm proving the adage that if you fix one thing on these rigs, you risk introducing problems elsewhere!

Have had my TS520SE on bench to replace the WWV RF amp FET which had blown. RX working perfectly now on WWV and is fine on all other bands all modes.

But now the transmit side has gone weird. It was fine before with 100W or so on all bands and a bit less on 10m and Ip 200mA.

Here are the symptoms I'm seeing. They are so erratic that methodical troubleshooting will be difficult so I'm hoping someone spots something simple I can check.

First off idle current is adjusted to 60mA.

The ALC seems much "livelier" than before when I am in June position and peaking it. Before I had to wind carrier up to full to get full scale ALC on 10m, now only need carrier halfway on that band and on lower bands I get full scale FSD with lower carrier drive than before (around the indicated 3 position).

Having peaked ALC with Drive, I can't get the plate to dip. When I switch to CW I see over 200W on external RF meter when I peak load and the plate current is only about 120mA. Something very weird going on so grateful for where to look!

Of course primarily, how are your tubes, then, you did check the plate bias potentiometer on the back bottom corner, right?
Dumb questions I know but I gotta ask.

My first geuss, and it is just a geuss without poking, prodding and metering around it myself, is dirty wafer switches and or switches, pots or plugs.
(Narrowed it down quite a bit for you, didn't I?)
The wafers in the HV cage is my #1 geuss. Discharge your tube plates before you get in there.
Other major players are the plugs that are everywhere, spray on Deoxit
(low pressure, Deoxit has a variable nozzle) Work each plug in and out a couple times.
A new technique I'm doing is to use a little spray on tiny brushes (less waste of expensive spray and less mess), scrub the prongs of plugs gently, then I apply "CorrosionX" with a small artists' paint brush (again less waste of expensive chemicals), then push plug back on, pull off, push on. I don't pull on the wires though, I grab hold with a 6" hemostat at the middle of each plug taking care not to damage any wires. On some I may also push each individual wire clip down further with a 1/32" blunt tip tool I've made (bastardized dental tools are your freinds!), getting it down to pin metal that hasn't been touched before. I'm using 2.25 power reading glasses and a magnifying lamp like the one on K4EAA's bench when doing this kind of work. (I should have been a microsurgeon). If you use any wire type brushes BE SURE YOU DON'T LEAVE ANY BRUSH WIRES IN THE CIRQUIT!!!
Nylon brushes would be safer, an old toothbrush or your XYL's makeup brush (snicker, snicker, somebody is going to get a rolling pin over the head for doing just that) they won't clean as well but they won't create shorts either.
I'm researching tiny brushes, I'll be making my own for certain appications. I searched Grainger Ind. supply yesterday for an hour to no avail.

Study up at KE4EAA.com and over at Hybrid Restorers site and you'll get some ideas where to start to fix your rigs' problems.
If using Deoxit take care to wait till boards are no longer wet. I just bought half of a TS-530S on eBay that had a fire on the RF board after using it.
I hope I'm helping, new to the game.

Subject: [TS-520_820_530_830] TS830S no bias

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

46269. TS-830S band switch rebuild -- which method?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-08 14:55:03 UTC
From: Craig Roberts
Topic: 46257 Message: 46269

For those who have rejuvenated their band switches, how did YOU do it and what have been the results??

The good news is that my thoroughly rebuilt TS-830S is again transmitting with full output on all bands. The bad news is that the culprit in its recent difficulties was the same one the radio arrived with a year ago -- dirty band switch. The symptoms were little or no output on 10 meters with intermittent low drive and output on 12, 15, 17 and -- sometimes -- 20. The power output increased progressively on the lower bands and 30, 40, 80 and 160 acted normally (at least for a while). With the classic low power on higher frequencies behavior I, of course, began by substituting a new driver. No joy. Then, new finals. Still no joy.

It was then that I first suspected the band switch, but the sudden onset of the symptoms led me away from that conclusion until later -- much later.

At any rate, all is well now -- for the time being. When I originally got the rig and cleaned the band switch, I was advised that, sooner or later, that pesky component would become problematical again. Well, here we are. While DeoxIT may have done the trick this time, I really should go to the trouble of removing the RF Board, disassemble the switch and service it using Ken's conductive paint or Jim Showker's wire bridge method.

Which do you prefer?

73 and Happy Holidays,

Craig

Hi Michael,

Thanks for suggestions.

Board was left in place during work, and TS520 has wire wrap not molex connectors.

But I'll open her up again and look for any stray wires - I was soldering and cutting leads so piece of wire may well have got where it shouldn't.

Mike,

I followed the standard procedure. I turned the POWER and HEATER switches on, placed the MODE switch to SSB, the METER switch to lp, pushed the SEND button and adjusted the BIAS control, but there was no reading at all. I then measured pin 5 in in the finals and saw no voltages in STAND-BY or SEND position. The only deflection on the TS meter is in HV in SEND position with voltages about 820 DVC.

A correction to my first mail. I do hear the t/r antenna relay when I key the transmitter.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

A little more detail on symptoms - I'm seeing well over 50W RF output when peaking ALC in Tune position! Have substituted a new 6146 for each output valve in turn but made no difference. What would cause output to go off the scale on a 200W meter in the CW position? ALC is definitely much higher than in past. On 40m I can peak it for full scale with Carrier below 2 on dial. 73 Adrian G4IQW

Regarding the bandswitch issue:
  I have been repairing some TS-530S / TS-830S RF Modules lately. I have been desoldering the switch sections off of the board, cleaning them with a mild solvent to remove traces of old cleaners/lubricants that had been applied, cleaning them with detergent, then next cleaning them with Tarn-Ex (a silver cleaner).
   After that I polish (with a tiny wire wheel on my Dremel) the exposed copper and the switch terminal (in the area around the rivet) and very carefully solder the two together. This is the neatest way and the quickest, however you need to be careful that solder does not flow up the switch contact area.
   I have done it using short pieces of tiny silver plate wire, by scraping the solder mask away from the PC board trace and soldering the small wires from the switch terminal to the PC board trace. This is a good method, but takes longer and is more tedious.
    The results are well worth the trouble, whatever method you use.

Hi Mike I was just about to log in to correct my error having had head deep in schematic, and saw your post. Had somehow got into my head that the pot adjusted HV, not indicated RF power, so am now not surprised it had no bearing on power measured externally! I'm really puzzled. The rig looks like it's magically producing 200+ W, but that's forward power and there is 100W reflected power from dummy load. Something must be very awry with the final tuner so that it's badly matched to 50ohm dummy load, but I can't figure out what. Ditto the apparent high output (60W) in tune position looks more like the 30W or so I usually get in Rune when you subtract the reflected power. Do you know how I can isolate the problem in the final output stage? 73 Adrian G4IQW

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the

final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

It's nothing like Deoxit D5. More of a lubricant
and as such should never be used near the band
switch wafers. Looking for trouble if you do.

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is

connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Topic: 46257 Message: 46293

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

73

Peter, OZ8CTH

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

From: Mike
Topic: 46257 Message: 46295

Peter,

What is the final Cathode voltage if the IP meter, in transmit,
indicates "60ma"? If you do not how then I recommend you watch my video
about the final tube cathode circuit and metering circuit. The video can
be viewed at the following link:

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/

As I say at the end of the video, you can change the IP meter current
value to any value you want, for example, 60ma in this case. You will
need a calculator to perform the "simple" math calculations.

46296. Kenwood Net Update (December 9, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-09 15:45:21 UTC
From: Mark Gilger
Topic: 46296 Message: 46296

The Saturday net on 40 meters had 13 check ins
under good band condition. There were 1 new check
ins, . We had the following number of radios checking in.

4 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
2 running TS-830S

I was using my TS-830s.

The Sunday□s 20 meter net had 20 stations
checking in under good band conditions. There
were 5 new stations checking in, WB6KVD, N7GIV, VE5HWH, KD0TKJ, and W5KAW,

Out of those, there was:

4 running TS-520(x)
2 running TS-530(x)
0 running TS-820(x)
2 running TS-830S
1 running 599D twins

I was running my 820 twins, TS-820s + R-820.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54
October 2013, Saturday☐s net total = 61, Sunday☐s total = 55
November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 13, Sunday☐s total = 20 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:

From: Peter Ravn
Topic: 46257 Message: 46297

Mike,

I have rechecked the voltages on the rectifier. On terminal 210A there are zero VDC, and on terminal 210B there are 264 DVC. If I bypass the open R11, I get 263 DVC on terminal 210A. No wonder that I see no voltages on plug 9, pin 2 on the RF unit.

Time to replace the open R11?

73

Peter, OZ8CTH

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73
Mike W5RKL

On 12/9/2013 1:49 AM, Peter Ravn wrote:

Mike,

There is no voltage on RF unit plug 9 pin2 (210A). On 210A on the rectifier there are 263 DVC, but zero on 210B, so where does that leave us?

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend

you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Emne: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Emne: Re: [TS-520_820_530_830] TS830S no bias

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

73
Mike W5RKL

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

Peter,

After replacing R11, measure the voltage at the RF Unit plug 9 pin 2 (210A) and the final unit "SG" terminal. You should see +265VDC on those 2 places. If you do then perform the normal bias setting steps to ensure the final tube's idling current is 60ma. If all goes well then go through the normal transmitter tune up procedures and you should see normal RF output on your dummy load's watt meter.

Did you get the email I sent you about watching the video? I recommend you watch the video so you will see how this works.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

46302. SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-09 22:29:03 UTC
From: Peter Ravn
Topic: 46257 Message: 46302

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

73

Peter, OZ8CTH

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

On 12/9/2013 10:26 AM, Peter Ravn wrote:

Mike,

I have rechecked the voltages on the rectifier. On terminal 210A there are zero VDC, and on terminal 210B there are 264 DVC. If I bypass the open R11, I get 263 DVC on terminal 210A. No wonder that I see no voltages on plug 9,

pin 2 on the RF unit.

Time to replace the open R11?

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73
Mike W5RKL

On 12/9/2013 1:49 AM, Peter Ravn wrote:

Mike,

There is no voltage on RF unit plug 9 pin2 (210A). On 210A on the rectifier there are 263 DVC, but zero on 210B, so where does that leave us?

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Subject: [TS-520_820_530_830] Ham Radio Silent Key

I know this doesn't pertain to Kenwood rigs, but it is important.

We lost another Ham Radio Operator this morning about 8:30 am EST. I stopped by this morning to see if he was ok and I found him in his chair where he slept most of the time. He was cold and no pulse. I called 911 and got the police and ambulance there. They called the coroner, His name was David Kuenzel. WB8TMR. He was my Elmer and got me started into ham radio 35 years ago. He fought Prostate cancer for 6 years. In fact He gave me my first TS-530s which I still have. I talked to his niece and Dave wanted me to have his radios and antennas. I will take them an use the well in memory of Dave.

Peter,

I'm sorry to hear of the additional problems you are experiencing with your 830.

I would not use those final tubes, even if they test GOOD in a tube tester! Replace them with "known good tubes".

It's possible the bias supply has failed which can lead to the final tubes conducting to saturation levels causing the plates of the final tubes to turn RED.

It's possible the source of the smoke you saw are the 4 final tube cathode resistors, they overheated due to the high current flowing in the cathode circuit.

Before you power up the 830 again, assuming you have thoroughly troubleshot the 830 and found the source of the failures and replaced defective components, set the rear panel's SG switch to OFF. This will prevent the final tubes from conducting in receive and transmit. This will allow you to perform additional troubleshooting with power applied. If the fuse blows again, do NOT power up the 830 after you replace the fuse!! You should never do that because there are obviously some additional problems you need to find and fix.

Peter,

I'm sorry to hear of the additional problems you are experiencing with your 830.

I would not use those final tubes, even if they test GOOD in a tube tester! Replace them with "known good tubes".

It's possible the bias supply has failed which can lead to the final tubes conducting to saturation levels causing the plates of the final tubes to turn RED.

It's possible the source of the smoke you saw are the 4 final tube cathode resistors, they overheated due to the high current flowing in the cathode circuit.

Before you power up the 830 again, assuming you have thoroughly troubleshot the 830 and found the source of the failures and replaced defective components, set the rear panel's SG switch to OFF. This will prevent the final tubes from conducting in receive and transmit. This will allow you to perform additional troubleshooting with power applied. If the fuse blows again, do NOT power up the 830 after you replace the fuse!! You should never do that because there are obviously some additional problems you need to find and fix.

On 12/9/2013 4:29 PM, Peter Ravn wrote:

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Mike W5RKL

On 12/9/2013 10:26 AM, Peter Ravn wrote:

Mike,

I have rechecked the voltages on the rectifier. On terminal 210A there are zero VDC, and on terminal 210B there are 264 DVC. If I bypass the open R11, I get 263 DVC on terminal 210A. No wonder that I see no voltages on plug 9, pin 2 on the RF unit.

Time to replace the open R11?

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is - 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are - 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from - 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Fra: TS-520_820_530_830@yahoogroups.com [mailto:TS-520_820_530_830@yahoogroups.com] På vegne af Peter Ravn

Emne: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

A new careful measurement gave another result. On the rectifier there are - 109 DVC in STAND-BY and - 107 DVC in TUNE. On pins 5 of the final unit there are - 96 DVC in STAND-BY and - 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Mike,

I followed the standard procedure. I turned the POWER and HEATER switches on, placed the MODE switch to SSB, the METER switch to lp, pushed the SEND button and adjusted the BIAS control, but there was no reading at all. I then measured pin 5 in in the finals and saw no voltages in STAND-BY or SEND position. The only deflection on the TS meter is in HV in SEND

position with voltages about 820 DVC.

A correction to my first mail. I do hear the t/r antenna relay when I key the transmitter.

73 Peter, OZ8CTH

Emne: Re: [TS-520_820_530_830] TS830S no bias

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs,

move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Topic: 6938 Message: 46308

Hi, guys.

I am pretty new still to the HF stuff, so I apologize for the quality of questions I have been asking recently.

I have an AT-230 and I was wondering if it is considered a 'balanced tuner'? I tried reading the manual, and it isn't clear to me. What I am trying to do is run ladder line from my dipole into the tuner and I am wondering if I need a balun or if this tuner will be okay without one? Can I use banana clips to clip each end of the ladder line to the antenna connector in the back?

Thank You,

Jason - K7BOG

I said to connect the analog DC volt meter "RED" lead to the "FG" terminal and the final tube socket pin 5 and "BLACK" lead to the chassis. Reverse the lead connections I mentioned, meaning RED lead to the chassis and the BLACK lead to the FG terminal and final tube socket pin 5.

A VTVM is best suited for the bias volt test I mentioned, it has a "negative" DC voltage measurement setting. If you have an analog VTVM, use it and set the switch to DC voltage measurement switch setting to measure "Negative" voltage then connect the leads as I said in my initial response this morning. However, if all you have is a simple analog DC volt meter then connect the meter leads as I said above, BLACK lead to the FG and pin 5 socket terminals and RED to the chassis.

Topic: 6938 Message: 46310

Jason,

The Kenwood AT-230 is not a "balanced tuner". The AT-230 is designed to work with both "wire" antennas such as long wire and inverted L type antennas, as well as unbalanced "coax" fed antennas.

When the AT-230 is used with a "long wire" or "inverted L" antenna connected to antenna "3" on the rear panel, a good ground counter poise is required (see the AT-230's manual, page 8).

From: Craig Roberts
Topic: 6938 Message: 46311

Hi Jason,

The At-230 is NOT a balanced tuner, although I did use mine for a time on my ladder line fed doublet with a 4:1 balun at the output of the tuner. Results were okay, but a 1:1 match was difficult if not impossible on many frequencies. Still, it worked after a fashion on 40, 20 and 17 meters.

I now use a homebrew "Balanced Balanced Antenna Tuner" designed by Rich Measures that utilizes a choke balun at its INPUT, a pair of matched roller inductors and a 250 pF variable cap. It employs just two controls and matches my 55 foot doublet perfectly on almost all frequencies 40 -10 meters. My AT-230 is still in line in bypass mode simply to utilize its SWR bridge and dummy load switch position -- and to keep my Kenwood lineup symmetrical :-).

If you are an ARRL member, you can download Rich Measures' original article from their online QST archives. It's also in Joel Hallas' book on antenna tuners from ARRL. (Nice book and good guy). The article is online elsewhere without illustrations. Just Google "Balanced Balanced Antenna Tuner." If you'd like, I can send you photos of my version and some more information on construction. It's very simple to build and very effective. I found the bits for it on eBay and at McMaster Carr for a total cost of about $75.00. The Palstar equivalent is literally ten times that much. (It is a lot prettier, though). Then there's a guy in the Netherlands who builds exquisitely crafted balanced tuners utilizing the very same circuit for around $1,800!

I like mine.

73,

Craig
W3CRR

Topic: 6938 Message: 46312

I have the AT230, and use a 135'dipole, fed with ladder-line, (450 ohm window line), into a 4-1 balun...and have for abt 10 years. I get close to 1 to 1 SWR on 80, 40,30, 20...and less than 2-1 on 10 and 160. It works well with my 520, 830, 820, and my ts950.

Date: 2013-12-10 18:03:45 UTC
From: Peter Ravn
Topic: 46257 Message: 46314

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms,
R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either,
so there was no need to replace them. But the screen resistors looked
somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I
carefully inspected the board and found no smoking gun. Finally I cleaned
the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you
mention. After a careful cleaning the pot now shows smooth change of
resistance when rotated. The resistance is now also identical on both
terminals.

I opened the final cage and removed the final tubes. In the cage there was
no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of
overheating.

This is status until now. I will continue the troubleshooting as soon as I
find time.

73

Peter, OZ8CTH

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma
idling current.

Unplug the main power, make sure the HV caps have bled down to zero before
you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly
check the Final Unit's Cathode and Screen resistors. If there is evidence
the resistors are damaged (overheated) or any of the resistors are out of
tolerance, replace all of them. For example, if you find 2 of the 4 cathode
resistors have overheated, replace all 4 of them with new resistors. The

same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You

need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is

available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

73
Mike W5RKL

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

Peter,

That's good to hear.

Let us know what happens when you power up the 830 (driver and both final tubes removed) and you monitor the final tube grid voltage, "FG" terminal on the Final Unit, with you DC volt meter (DC volt meter's BLACK lead to the FG terminal and RED lead to chassis and voltage switch set to 200VDC or higher) while adjusting the bias pot in transmit (USB or LSB mode).

46316. Another issue with 820 no drive

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-10 19:16:25 UTC
From: n8nma@...
Topic: 46316 Message: 46316

Well got the digital readout working. Seems one of the pins on the digital readout board was loose. Now there is no drive level and so no output. Any idea where to start. Tried a new 12by7a and that did nothing.

Thanks

Tom Jones N8NMA

Hi Steve, the Best "Balanced tuner" I have seen (and I bought one) is the MFJ 974. The old Johnson matchbox tuners were also good but are now collectors items and pricey. Many tuners that have a "balanced" input have a fixed ratio balun transformer inside and that is not my Idea of vertatile for a variety of X and Z that you may have at the end of your feedline.
My 974 has a better way of working with the balanced feedline tuning. I put up a 90 ft dipole as an experiment and still use it over a year later on 60, 40, 30 and 20M with good signal reports.

I just built a 135' Off Center Dipole w/a 4:1 balun.
It works fine on 80, 40, 20, 17, 15, 12, 10 and 6m without a tuner.
Your dipole should work fine w/o a tuner.
Also use a G5RV Jr on 40, 20, 17, 15, 12, 10 and 6m again w/o a tuner.
The trick is to keep antennas way away from the shack, as in 100 feet or
more away.
The amt of coax I use is obviously making a diff as well.
Since a tuner doesn't actually tune anything, just fakes out your radio, and
if using a hybrid you "tune" the radio anyway, I do not use tuners.

Anyone know where I can find matching paint for the covers on my R-2000? Its different from my other Kenwoods. I havnt seen any references to paint for it on the net so far...

Thanks

You can take the cabinet/top to a local paint store and could possibly
use their computer and come up with the color mix for you.

Tom:

I did not see a response to your TS820 issues? If someone is working with you on this problem let me know as you dont need too many cooks.

Couple of clarifying points:
1. By No Drive am I correct in assuming you have no ALC meter indication in Tune mode when you are adjusting the Drive Control and this is true for all bands?
2. By No RF Output power am I correct in assuming you see nothing with the panel meter in the RF relative power position or on an external Wattmeter?
3. Did the radio previously load properly? Did you have good ALC indication?
4. I assume you are experienced at loading the TS820?

With no ALC indication and no RF output it would appear that it is not just an ALC indication problem. It is possible to have no ALC indication and still have good RF output, but that does not occur often.

Try this:

1. Power and heaters on.
2. SG switch off
3. Meter in ALC, VFO approx 200, Drive control 1200
4. CAR level pot full CW
5. Tune mode
6. Flip to Send and adjust the Drive Control for a peak in ALC indication. If no indication then try in CW mode. If meter pegs full scale at any time simply reduce the CAR Level pot to get it off the peg. Adjust the Drive control thru its range and not just around 1200.
7. Perform this test on all bands.
8. Good rig should produce full scale ALC indication with CAR Level pot advanced below 1200 or position 5.

For good ALC indication (RF drive) you need couple of things:
1. 6146 tubes with good filaments and heater power on so you have cathode emission.
2. RF voltage swing at the control grids of 6146 finals that is in excess of the operating bias offset voltage. For a TS-820 that is approx 47rms rf volts at Pin 5.

Do you have an RF probe and VTVM? If not, then an O-scope? Needed to troubleshoot loss of RF drive. With either of these instruments and the TX Level Diagram relatively easy to find where RF drive is weak or missing.

Terry K9TW

Topic: 46257 Message: 46322

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then

install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

46323. SV: SV: [TS-520_820_530_830] TS830S no bias

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-11 18:30:16 UTC
From: Peter Ravn
Topic: 46257 Message: 46323

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the

DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to

perform any of these test/voltage measurements when you are tired.

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode

resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You

need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is

available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Emne: Re: [TS-520_820_530_830] TS830S no bias

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

73
Mike W5RKL

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

Also noticed that the digital readout reads 22 MHz in the 28 MHz band position but is ok in all others. This radio belongs to a friend. I have a 520 S so somewhat familiar with the radio.
Thanks

Yes familiar with the radio and operation. Have all test equipment needed. And just noticed that it will work in FSK mode but no other mode. Or no output in any mode except FSK? Going to try the procedure you showed.

Thanks

There is a man on Ebay who sells paint to match Kenwood products, if you do a search there, you can find him. He might also be able to take requests if he isn't carrying that particular color.

OK

Could you previously peak the ALC indication in Tune or CW mode since rig has been in your possession or is this a recent acquisition that came with this problem?

It is early to say, but might have a bad IF xtal filter. Does it have the CW filter in it?

You can try obtaining ALC indication in SSB mode by bringing the mic gain up and keying the mic PTT and whistling in the mic. This way you are going thru the SSB IF filter. If you get ALC indication in SSB mode then pretty safe bet the CW filter is bad or a bad CW filter switching diode. .

Topic: 46316 Message: 46330

Well, now I've done it! In the last moments of aligning my TS-830S after performing extensive service on it, I have managed to absolutely destroy the core of the 28 MHz RF tuning coil. All others adjusted nicely.

So, now I need a replacement for this component on the RF Board:

L21 L34-0995-05 28 MHz RF tuning coil

Does anyone have such a thing?

Many, many thanks and 73,

Craig

Try emailing Jim at Hybrid restore,
He's quick to reply. I'd bet he'd know the part # and could tell you if Mauser or someone had it.
A 530S RF board sold 5 days ago on eBay for $50 or so. I just missed it.

So if it is the CW filter removing it and changing the plug below should tell this ...correct?

Well it does have output in SSB so it must be where you said, the owner said he never used it in CW so never tuned it that way??? Oh well going to look at filter. And the diode. The filter had a loose solder joint but that didn't change anything.

Try moving the IF2 plug to the A position. The SSB filter will be selected regardless of the mode. Should be able to get ALC deflection in Tune mode and load in CW mode.

This should allow you to use the rig and then can trouble shoot the CW filter path by signal injection and measurement.

Pg 34 of the Owners manual shows the plug positions and study of the main schematic and the mode switch deck S6-1 shows how 14vdc is directed via the wiper of this switch to the IF board.

Not sure if you can find past message numbers in the archives on this subject or not, but not too long ago this same issue was dealt with in some detail including confirming that both CW filter switching diodes were good and getting necessary turn on bias voltage. Also discussion on how to sweep the CW filter to verify the center frequency. I will see if I can find this so wont have to repeat all the typing.

That doesn't make a lot of sense, you can't tune it without using CW mode.

Michael,

Craig provided the part number in his text that he needs:

L21 L34-0995-05 28 MHz RF tuning coil

The part number Craig provide is shown in the TS-830 service manual's
part number under "RF UNIT" parts.

Craig,

Check with Bob Mansker, ke5ftf@..., he most likely has that part.

Another thought, some boards go for not too much on eBay, $20-$80 or so.
If you can't get just that one coil I'd bet that same coil is used on several other models if not all of them.You'd need to check the parts list and compare component numbers but if you have difficulty getting just that coil this might be a solution. One fellow, charro88 I think, makes a living chopping up Kenwoods, on eBay, sad deal.
He's got 4 radios cut up right now. Make him an offer if he's got a board that would work, he's a little negotiable. I've bought some components from him. His skills with the english language are lacking however, an immigrant I think, but he seems ok.
Just do a search for Kenwood TS or Kenwood parts, on eBay, you'll find what you need if you don't get it from KE5FTF.

Not true.

You need to study how the rig produces a DSBSC signal and how that becomes a TIF signal to provide RF drive for the Transmit Mixer. One of the first and key building blocks in a SSB transmitter is the Balanced Modulator.

A balanced modulator is a mixer. KW hybrids use a diode ring modulator. It is a key stage in a SSB transmitter. It has two inputs....low level Audio and high level Carrier.

The BM produces a DSBSC output in two ways:
1. Unbalance the ring diodes by applying a variable 0.0 vdc to 0.70 vdc bias voltage to turn on diodes. This is what the CAR Level pot does. We do this to Tune the rig and to operate CW mode.

OR

2. Input audio into the Mic line. Can be done by whistling or connecting audio generator and injecting 5mv to 10 mv at 1200 hz. We do this in SSB mode.

With either method you can peak the ALC indication with the Drive Control.

Method two obviously isnt the preferred method, but can be used to confirm if the rig is capable of producing TIF signal from the IF board.

In a pinch you can load rig this way if for example CAR Level pot dc voltage is unavailable. Not very convenient to have to hook up your audio generator to the Mic line to routinely load the rig.

Hey, y'all,

Many thanks for the suggestions concerning the RF coil replacement. Here's the skinny:

Bob has no RF boards to part out,but may have one next month for eBay auctioning.

From examination of parts lists, it appears that none of the RF boards from other Kenwoods now offered on eBay contain the coil I need. Strange but true. I may buy one anyway to cannibalize a slug from a similar coil if I can extract the remains of my broken coil slug. I am considering super gluing a small diameter dowel to the top of the broken slug and try to back it out. It'd be nice if I could avoid removing the RF board altogether and risking damaged connectors. I have found these boards to be relatively fragile. The copper traces are insanely thin, as you know.

Any other suggestions would be most welcome.

Thanks again and 73,
Craig

I found one from an old CB unit that I had that had died years ago. My 530 and 830 have the same RF board.
Also if you remove the audio board there is a plate you can remove to access the bottom of the RF board with out removing the board.

I like the possibility of gluing a dowel to the cracked slug. Might try to get some lube Or penetrating oil in there to ease it out, but then if oil got on top the glue may not stick, hmmmmmm, how about glue the dowel, keep it small diameter, say 3/16" and keep the quantity of glue to a minimum like one drop or wet the end and remove any excess. (or you may glue it in place and never get it out).
After your glue is dry, gel might be better, then spray it with Deoxit to lube the slug, that would evaporate later and not leave oil in the coil.
The fellow that is destroying (parting out) perfectly good radios is charro815 (had the number wrong before) I have a hotlink to his eBay store:
http://www.ebay.com/sch/charro815/m.html?_nkw=&_armrs=1&_ipg=&_from=

Remember his facility of English is lacking, so keep your communication with him simple and to the point. He will dicker a little bit. I don't think he's selling a whole lot this month so he could use the money.
Tell him Michael sent you, I'd appreciate it. I'm trying to befreind him, he'll be more likely to consider my low offers if I can.
I made a lowball offer on a set of Knwd tubes this morning that he didn't accept. I told him if he could get a tube checker and learn to properly test tubes that if they tested close to new strength that they'd be worth $50-$60, more than he's asking, $40 "buy it now". I also explained to him that buying untested used tubes is a gamble, only about 1/3 are any good. That I've had pretty bad luck and I'm TRYING not to buy any more used tubes. He said I seem to be a good man, so I think he's OK.
Gotta get a TS-820 finished today and listed on eBay.Good luck with the dowel idea, let us know how it works.

Craig:

You are correct that none of the other KW hybrids with exception of the TS530 and TS830 use this Mixer coil. It is the same as the L12 Ant coil. You cannot just swap for other "similar" coils as you will note no capacitor across this coil. This is because it uses the circuit parasitic capacitance to form a 10 meter parallel resonant circuit. That parasitic capacitance consists of not only the contribution from the PC board foil traces but the inter-electrode capacitance of the Driver tube.

As you know RF boards (especially TS530/TS830) come at a premium when/if you can find one and there is a reason for that. Also, very few people have any RF boards that they use to harvest parts from. Worth a try asking.

Your best bet is to try the super glue method to remove your cracked core.

You may also be able to use a burr on a Dremel Tool and grind out the core if you cant remove with wood dowel and super glue, but easy to damage the bobbin and windings trying to drill or grind out the core. Must of course carefully clean all the ferrite powder/dust residue.

Bill is correct you can access the foil side of the RF board by removing the metal access plate below the Audio board, but it only exposes the soldering and there is no board thru hole to access the other side of the ferrite core. I cant remember if there is a hole in the bottom of the bobbin or if it is a blind hole?

If you are not successful with core removal check back with me after first of the year as I may have a line on a parts special TS-530.

Gordon:

I re-read your post. I thought you were questioning my suggested troubleshooting test to see if there is ALC indication (and of course accompanying RF output) when whistling into the mic in SSB mode.

Here is what I thought you were responding to.

"You can try obtaining ALC indication in SSB mode by bringing the mic gain up and keying the mic PTT and whistling in the mic."

I see now you were questioning the former owner saying he never loaded in CW mode. It is very doubtful that he whistled or held a note into the mic, or held the mic up to a code practice oscillator speaker, or injected audio into the mic line to routinely load in SSB mode. Any and all will work if you can sustain a note. Of course injecting audio in the mic line works just fine.

Not uncommon for old timers or experienced SSB contest operators to retouch up the loading on the fly when QSYing up and down the band by just peaking the Drive and adjusting the Plate Tuning by speaking (threeee or fiiiiiive) or whistling in the mic. They have no time to go back to Tune or CW modes and touch up the loading.

Some people really have no understanding of what they are doing when loading one of these rigs. No concept of what ALC indication is telling them.

This former owner probably meant he never operated CW but that does not mean he wasnt loading the rig in CW mode as we all normally do.

So I stand by my original response that you do not need to be in CW mode to load the rig, however it is the normal method that we all employ and I would say it is very unlikely that the former owner loaded in SSB mode.

I have done the super-glue thing with old tube radios. You know, back in the days when they were repairable and it was worth the bother, before we became the society that is going to be built on nothing but land-fills?

Anyway, that rant is for another time and place. The main thing was to use the THICK superglue, the sort that model airplane and various other precision model-makers use, for one thing. The other 'trick' is NOT to use a wooden dowel. Dowel, yes. Wood, no. The glue soaks in too much to 'grab' quickly.

I've been thinking about this, and looked around the house for odds and ends that would work for this. A 'swizzle-stick" sort of coffee or possibly iced-tea spoon sort of thingummy, from one of the fast-food places looked promising. (I can't tell which sort, don't patronize those places much, if ever.)

There were several odds and ends of packaging material, such as the thick edge-pieces of those insanely-hard-to-open plastic bubble packages, that if trimmed square and cut off flush and even, would probably be OK as well.

I used a piece of thin lexan I had tossed in the trash, from another project. It was a few inches long, and about 3/32nds of an inch square-ish. The cracked slug was a bit more than twice that diameter, I think.

One tiny drop of light oil on a toothpick around the edge of the coil form to keep the cyanoacrylate from getting into the threads, one bigger (but still small) droplet of the glue on the end of the plastic stick, press it in against the center of the slug, and then WAIT a minute or three.

No matter what I've ever glued with cyanoacrylate, be it balsa or bronze, it always seems to work better if I don't try to rely on the "instant" part of the advertising hype. Three or four minutes, instead of 24 hours (for white glue or similar), seems quite instant enough when you think about it. For some reason, though, we all seem to be in a big hurry and want it -NOW!- instead of three minutes from now.

Give it some time to set, for the love of Pete, don't do what stupey old me does all too often, and try to rush things.

I would be willing to bet that your idea works on that coil, at least as well as it did on that old three-tube regenerative shortwave receiver I did it to twenty or thirty years ago.

(Maybe I'll take that back up one of these days, if I can find some old tube radios to fix. I always enjoyed that, and the circuits are so bloody simple compared to modern, digital stuff in particular. Quite restful on the mind by contrast.

And to think, when I was a dumb kid I had trouble with those kinds of things, because of their 'complexity.' Little did I know what was coming down the pike, straight at me. didididit didit.)

There's a TS-830S Rectifier Unit board being sold on eBay for $20 plus $5 shipping. The eBay ID number is 400622364893. Go to ebay.com, put that ID number in eBay's search box and click search and the ad will come up.

I mean no disrespect towards the eBay seller who is selling the TS-830 Rectifier Unit board shown in that eBay add. However, can you find what's wrong with the board he is selling by simply looking at the component side picture in his ad?

His ad says the 830 receiver worked fine but the transmitter had no output. He further says he found a bad resistor on the final board. He then said the Rectifier board was probably okay but there were no guarantees. The issue is not "there's no guarantees" statement. That's more often than not to be expected when selling used equipment.

However, can you see what is wrong with the Rectifier Unit board he is selling and what could easily have been the source for the resistor failure on the final unit board he says in his description? Also, what other possible failures in the final amplifier/final unit board could have possibly occurred that he may not be aware of by looking at the Rectifier Unit board he is selling?

No, I didn't destroy it, but a diddle stick happy CB'er did. He thought he could get more than 100 watts output.
In fact he destroyed more than one slug. When he moved out of town, I helped him move and found this 530 in the closet and he gave it to me for helping. First thing I did was rip out the CB mods and restored it to 10 meters. That's when I found out what he did. Took me 3 days to get this rig back up and running. Even the band switch wafer for 10 meters was burned. you had to wiggle the band switch to get 10 meters. I repaired it with some silver solder and got it to work, but I don't know how long it will last. It is crazy what some unknowing people can do to these rigs. In my opinion, this line of hybrids rigs are the best that Kenwood ever built. You have to treat them with respect. Like one ham on here says "Real Radios Glow in the DARK"

Topic: 46351 Message: 46356

The 470 Ohm resistor on the rectifier board is usually toast too.
I just bought another 820S Tuesday, making 5 total here!!!
I just bought the RF finals board, Rectifier board for 820S and a 430 LPF board, to get the small relays, hoping they match the relays in LA-1000 amps (I have 2 right now), one pristine and one beater I've restored), for $60 delivered.

The damage you will find on the finals board would be the (4) grid resistors, the 1/2 watt 20 Ohm that act as fuses. Don't "super size" them as Ken, K4EAA.com (http://www.k4eaa.com/examples.html) would say. He has a page showing what happens when you increase the wattage rating of resistors there to keep them from burning up. Can't find it right now...
Kenwood designed them to act as fuses protecting the other components.I just replaced (10), yes 10, 33 Ohm 1/4 watt resistors in parallel that replaced them on one radio, I think the "oldham" that went silent key must have bought them for bulk quantity price.......
The TS-530S I've nicknamed "Old Dog", looks like he went through WWI in the trenches.
10-33's in parallel make 3 Ohms, real high wattage, too high current, and is probably why he had fires on that board and the Rectifier board.
"Old Dog" is the the brother of "Pretty Sister", the pristine, perfect low miles TS-530S I had for sale on eBay, came from the same estate.
I've got 20 or so hours into "Old Dog" and not done yet.
The other damage you will find is R11 on the rectifier board. A 470 Ohm resistor. Had a fire there too......
I had a man contact me on eBay, try to give a bunch of knowledge but his letter was lost because it contained an email addy, eBay clips the emails.
He later contacted me by Personal email, found it on my QRZ page I'd geuss. He said he found by trial and error that the GE 6146W tubes are not biased right for Kenwood Transceivers, the hard way by burning up some boards using the GE W's.
I believe He's right and that they are the source of many fried Finals and Rectifier boards. I won't be using any. Sylvania 6146W seem to be ok however.

46358. TS-520 Lock Screw on Load control linkage hitting driver

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-13 16:10:20 UTC
From: <bgaston@...>
Topic: 46358 Message: 46358

Just picked up a TS520 of "unknown condition" and have it up and putting out full power on all bands.

Noticed a "catch" last night on the load control, and opened the cover to find one of the screws on the shaft coupling that sticks out further than normal and is bumping the driver tube as it goes by. The shaft is keyed/flatted on one side so only one screw can go far enough into this coupling to clear the driver tube, and there are two on it.

I will put a photo in the album if you'd care to see what I'm talking about.

Secondly, is the metal piece running up the side of the driver tube supposed to be outside or inside the tube covering the valve?

Thanks.

Michael,

You said:

"the finals board would be the (4) grid resistors, the 1/2 watt 20 Ohm that act as fuses".

No, unfortunately, not true.

The "4" resistors you are referring to are not "grid resistors" but rather they are "cathode resistors" and they do not act as fuses as you have also said they do.

The cathode resistors in the 520, 820, 530, and 830, act as meter shunts, allow for a voltage drop to occur during transmit when current flows in the cathode circuit. This voltage is then applied to the metering circuit resulting in a significant decrease in DC voltage caused by voltage drops that occur in the meter "multiplier" resistors, reducing the voltage down to the "mv" level, that is then applied to the meter through the "IP" meter switch setting. The metering circuit in the 520, 820, 530, and 830 hybrids measures "voltage" even though the meter's top scale is registering "current".

The Rectifier Unit board shown in the eBay add is not from a TS-820 but rather from a TS-830. None of the resistors on the TS-830 Rectifier Unit board pictured in the eBay ad show any signs of being "toast" (overheated) so that is not what's wrong with the Rectifier Unit board.

Michael:

With all due respect:

1. "Grid Resistors"???

Do you mean Cathode meter shunt resistors? Or are you talking about the SG grid stopper resistors?

Are the cathode meter shunt resistors in a Yaesu FT-101, Heath HW-101, or Drake T4X "fuses" as well? Are they designed to blow to protect "other components" ? Wonder how often they blow?

Ken Kempski is a smart man and a friend but I do not want my cathode resistors blowing open. I like to keep my panel meter. Take a read on KW hybrid cathode resistor topic on W8JI Tom Rauch website.

2. "GE 6146W tubes are not biased right for Kenwood Transceivers"???

What does this mean as no vacuum tube comes "biased"? Please elaborate.

Your hybrid wont know what 6146 is in the socket. Any and all will work just fine. Best to not mix no suffx or A and B as they have slightly different inter-electrode capacitance, but any brand other than the new Chinese will work just fine. No need for matched pairs as we are running parallel and not push pull.

I am sorry but this is starting to get pretty scary and a bit concerned for our newly licensed and first time KW hybrid owners that may be taking notes on this.

Someone has either changed the screws or shifted the coupler on the shafts closer to the tube shield. Screws should be same length and one will sit flush and other will show 2 or 3 threads. Maybe loosen all four screws and shift the coupler slightly toward the PA cage. Only one screw should ever come close as the rotation is limited to 180 degrees.

The ground strap needs to be on inside of the black metal tube shield.

Topic: 46362 Message: 46367

Eric,

The N3ZI DDS VFO kit being sold by Doug, N3ZI, is a nice VFO, very stable, and has a typical upper frequency limit of 40Mhz. I have 2 of them, one I use to control a converted Johnson Messenger 223 on 29.0Mhz 10 meter AM.

The DDS VFO's out signal level is 250mv into a 200 ohm impedance. Although the DDS VFO manual states the output impedance doesn't have to be matched to the circuit the VFO's connected to, if the impedance is not matched the VFO's output spur filter will not be as effective as it would be if the VFO output impedance and the impedance of the circuit the VFO is connected to are the same or very close to 200 ohms. An impedance mismatch not only will result in higher spur output but also a significant reduction in the VFO's output signal level. Depending on the circuit you are considering using the DDS VFO with, a small amp may be required between the VFO and the circuit the VFO is connected to.

You might search the web for "DDS VFO Amps", there are a few out there you can build.

I commented before I saw your picture.

It appears that the coupler has rotated. Most of the older TS520 rigs have ceramic coupler and not phenolic and have one screw that is flush on coupler hub.

Might have to use a right angle Phillips and loosen and rotate and re-tighten. Suggest you see if you can slip it toward the PA cage enough to clear the tube shield and if not will have to be rotated. I would remove top cover of PA cage so can observe position of the Plate Load cap plates and make sure they are fully meshed at full CCW rotation. Make sure rig unplugged and HV caps discharged.

All this talk of cathode resistors has got me wondering.

The stock cathode resistors are carbon composition, and on my 520 when I got it they had cracked and split. Now, the advice not to "super-size" them is sound, and the idea that wirewounds won't work because they're inductive seems intuitively obvious.

But! I've seen plenty of stuff that does have wirewounds in the cathode at RF, including hoofing great marine sets with PA valves like pickle jars. Not to mention the array of disc ceramics around the cathode circuit. So, I figured why not stick in the 10 ohm 7W wirewounds that I actually have on the shelf, instead of ordering up resistors and waiting for a few days. So I did. This is when I discovered something quite surprising.

I couldn't find a sniff of RF on the cathode, with my oscilloscope. Nothing. Well, maybe a wee ripple on 3.5MHz at full bore but certainly not enough for weird reactive effects to come into play in the resistors, we're talking about millivolts at most. But not only that...

There was hardly any audio across the cathode resistors. The cathode voltage unsurprisingly followed speech and showed a wee bit of speech "waveform" on low-pitched vowels, but with a normal SSB two-tone test it was again just the tiniest ripple.

I've since found a few people who say that wirewounds are just fine for the cathode resistors in these old rigs, but a roughly equal number who say they aren't.

The "cathode circuit" is part of the DC voltage current path in the
final amplifier tube. The RF chokes in the Screen and Plate circuits,
block the flow of RF from flowing through the screen and plate supplies
so there is no RF of any significance in the final tube's cathode circuit.

The cathode resistors are not fuses that open when the final amplifier
is improperly tuned.

I made a video that explains the voltage drop across the cathode
resistors (cathode voltage) in the TS-520 and TS-820 and the cathode
voltage is applied to the IP metering circuit resulting in millivolts
applied to the meter in IP postion. You can watch the video at the
following link:

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/

I said:

The "cathode circuit" is part of the DC voltage current path in the
final amplifier..."

The word "voltage" should not be there, the statement I meant to say is

The "cathode curcit" is part of the DC current path in the final
amplifier..."

Gordon:

In theory should be no RF at cathode of grid driven Class AB1 RF amplifier because should require no RF power to drive the finals in this configuration. All we need is RF voltage swing at the control grids (approx 47 rms or 133 p-p rf volts). Zero current X 47 rf volts = Zero power. So all we are doing is turning that 900vdc on and off at an RF rate. We then use the tank circuit to make something useful out of those current pulses.

If we never draw grid current the grids of the finals present a load which is conductance. When we have full ALC (with approx 45 ua of grid current) then the control grids look resistive at approx 500 to 1000 ohms. Instead of a swamping resistor from control grid to ground (as you might find in a high power class AB1 linear amp) KW engineers used a parallel resonant circuit shared by the Driver stage and Final control grids to present a more stable input impedance.

In practice the 6146 finals do require some RF power to supply charging/dis-charging current for the inter-electrode capacitance. We have Cgp and Cgk which are low values of capacitance from control grid to plate and control grid to cathode. Also inside the tube there is small amount of inductance in the cathode leads Lk and outside the tube small inductance from cathode pin to chassis ground thru foil traces and resistors that we label as Lk1. Lk and Lk1 are in series.

What this means is there will be some very small amount of RF current charging and discharging this capacitance and feeding thru this cathode inductance to chassis ground. It turns out that it requires approx 2 watts of power from the 12BY7A tube to provide this RF charging and discharging current.

To address this feed thru rf current thru Lk and Lk1 we use RF bypass capacitors from cathode to ground and as you note in your TS-520 there are 6 disc ceramic bypass capacitors in parallel.

If you have ever seen a Yaesu FT101 or FT102 you will notice they use a single cathode meter shunt resistor to ground. It is a small coil of nichrome wire that measures approx 0.60 ohms. I dont know how much inductance it presents in series with the cathode, but it seems Yaesu engineers were not concerned about using an inductive meter shunt. Not uncommon to see the white glass insulating sleeve over this resistor discolored from high cathode current in these Yaesu rigs. Abuse?

So I dont know what inductance value your new wire wound cathode resistor meter shunts present, but I am not surprised that you see no or very little rf current across them. Perhaps if you have another and a LCR bridge you could measure the inductance.

One problem with too much inductance in the cathode circuit is the small rf current flowing causes an IR drop across the tube grid to cathode and due to the phase relationship it will result in the input conductance dropping which means more RF drive requirement and that will increase as you go up in frequency toward 10 meters.We are running the 12BY7A just about maxed out as it is.

I have to admit with all the testing I have done I have never looked at the 6146 cathodes for RF current. You have piqued my interest. Might be fun to look at it with the bypass caps removed.

Ron:

It appears you are looking for an ALC transistor. It is unusual for it to fail. I hope you have not had a 6146 tube arc over to the control grid and to the FG line. Kind of unusual as arc over normally gets the beam forming plates and cathode.

Can lose a lot of components if that has occurred including series choke L3 and burn the RF board at Q10 and maybe burn up the bias voltage adjust pot. Just about have to inspect everything in the path back to -C power supply.

Curious if it is Q10 that you have diagnosed as failed?

Subject: [TS-520_820_530_830] TS-520 Lock Screw on Load control linkage hitting driver

Just picked up a TS520 of "unknown condition" and have it up and putting out full power on all bands.

Noticed a "catch" last night on the load control, and opened the cover to find one of the screws on the shaft coupling that sticks out further than normal and is bumping the driver tube as it goes by. The shaft is keyed/flatted on one side so only one screw can go far enough into this coupling to clear the driver tube, and there are two on it.

I will put a photo in the album if you'd care to see what I'm talking about.

Secondly, is the metal piece running up the side of the driver tube supposed to be outside or inside the tube covering the valve?

Thanks.
BG

Yes, I mispoke. I'm old, goofy, and ignorant.
The reference to the GE 6146W not being good in the Kenwoods is from another man that gave me alot of info yesterday. He said he burned up 3 or 4 boards using the GE W's and that his conclusion was something is not right with them in Kenwood transceivers. Obviously not bias, those were his words.

Again, from Kens' website:
Damaged Cathode Resistors
If a rig appears to load up properly, with sufficient plate current and good high voltage, but suffers from low output, the answer is many times the cathode resistors. Kenwood uses these resistors as fuses, to protect the finals and power transformer if the rig is mistuned for any length of time. The resistors will overheat, start to climb in resistance, and maybe even burn and rupture. In the picture below, the larger 1W 10 ohm resistors are in series with the cathodes of the 6146B's. In a rig that's been abused, these resistors may look fine, but actually be high in value from being overheated. The only way to tell is to measure them. Being in parallel, they should measure a total 5 ohms to ground. The plate current metering is derived from these R's, and will read much higher than it's actual value if the resistors are damaged. I replace them with 10 ohm 1W metal film units, to maintain the safety that they provide as pseudo-fuses.

I suggest you also go debate the fuse theory with your freind Ken. I'm sure he knows what the difference between grid and Cathode resistors is however and will not mispeak.
Pardon my mispoken tube part name. Forgive my ignorance, I've been away for a bit.
Man, tough croud today.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael:

With all due respect:

1. "Grid Resistors"???

Do you mean Cathode meter shunt resistors? Or are you talking about the SG grid stopper resistors?

Are the cathode meter shunt resistors in a Yaesu FT-101, Heath HW-101, or Drake T4X "fuses" as well? Are they designed to blow to protect "other components" ? Wonder how often they blow?

Ken Kempski is a smart man and a friend but I do not want my cathode resistors blowing open. I like to keep my panel meter. Take a read on KW hybrid cathode resistor topic on W8JI Tom Rauch website.

2. "GE 6146W tubes are not biased right for Kenwood Transceivers"???

What does this mean as no vacuum tube comes "biased"? Please elaborate.

Your hybrid wont know what 6146 is in the socket. Any and all will work just fine. Best to not mix no suffx or A and B as they have slightly different inter-electrode capacitance, but any brand other than the new Chinese will work just fine. No need for matched pairs as we are running parallel and not push pull.

I am sorry but this is starting to get pretty scary and a bit concerned for our newly licensed and first time KW hybrid owners that may be taking notes on this.

Yes, cathode resistors, I mispoke, thank you for catching that.
I even went and looked at the schematic before I posted because I keep catching myself doing that often. That little thing in the bottom of the tube picture, huh?
Pin #1. cathode.

Yes, those are also meter shunts.
From K4EAA's website:
Damaged Cathode Resistors
If a rig appears to load up properly, with sufficient plate current and good high voltage, but suffers from low output, the answer is many times the cathode resistors. Kenwood uses these resistors as fuses, to protect the finals and power transformer if the rig is mistuned for any length of time. The resistors will overheat, start to climb in resistance, and maybe even burn and rupture. In the picture below, the larger 1W 10 ohm resistors are in series with the cathodes of the 6146B's. Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael,

You said:

"the finals board would be the (4) grid resistors, the 1/2 watt 20 Ohm that act as fuses".

No, unfortunately, not true.

The "4" resistors you are referring to are not "grid resistors" but rather they are "cathode resistors" and they do not act as fuses as you have also said they do.

The cathode resistors in the 520, 820, 530, and 830, act as meter shunts, allow for a voltage drop to occur during transmit when current flows in the cathode circuit. This voltage is then applied to the metering circuit resulting in a significant decrease in DC voltage caused by voltage drops that occur in the meter "multiplier" resistors, reducing the voltage down to the "mv" level, that is then applied to the meter through the "IP" meter switch setting. The metering circuit in the 520, 820, 530, and 830 hybrids measures "voltage" even though the meter's top scale is registering "current".

The Rectifier Unit board shown in the eBay add is not from a TS-820 but rather from a TS-830. None of the resistors on the TS-830 Rectifier Unit board pictured in the eBay ad show any signs of being "toast" (overheated) so that is not what's wrong with the Rectifier Unit board.

Well! I've got wire wounds in my 820S and there should be no problems at all. They were well bypassed by disk ceramic capacitors already. To be sure I added extra ones of higher value in parallel. This makes sure that there are NO resonances in the final cathode circuit.
BTW the original carbon resistors were being slowly cooked out of spec, this often happens with parallel connection as one resistor tends to take more of the load than others due to tolerances.
As long as the value of the resistors are correct there is no reason at all not to use wire wounds. If you REALLY need the resistors to act as a "fuse" then you are either over driving the finals or have no idea how to set up a linear amplifier.
It seems a pretty weird place to use resistors as a fuse!

OK if you cant find a 2SC856 or NTE sub might be easier to find a 2SC1515 which will work and is used in the other Hybrids for this application, but will have to switch the leads around in the socket. Look on ebay and as I mention do a real good visual as unusual to lose a ALC transistor. Might consider buying several as you dont really know the root cause of the failure.

I think you are going to get an award for having the worse TS520 of all times! I dont have the patience to work on these hacked ones any more and no money in it. Never know if you have found all the mods and problems until you perform a complete service manual alignment.

Good luck

Hi all, I'm new to the group, and a new Technician as well. I recently purchased a clean TS520. I did the DeOxit clean-up, got all the scratchiness out of the switches and potentiometers. The radio tunes up fine on 10 meters, and does right at 100 watts. The problem comes when transmitting on SSB. I can listen and hear my transmission through another monitor rig, and it sounds fine. The problem is the output is intermittent. I have tried two mics with the same outcome... no power output on SSB. Out of the blue, the power will come on strong, and I have gotten good audio reports when it is working right. I can hear the relay click when I key/unkey the mic. I have done extra cleaning of the mic gain/compressor/carrier potentiometers. The problem is still intermittent. Is there something else I should be looking at to fix the problem?

Michael,

You said:

"the finals board would be the (4) grid resistors, the 1/2 watt 20 Ohm that act as fuses".

No, unfortunately, not true.

The "4" resistors you are referring to are not "grid resistors" but rather they are "cathode resistors" and they do not act as fuses as you have also said they do.

The cathode resistors in the 520, 820, 530, and 830, act as meter shunts, allow for a voltage drop to occur during transmit when current flows in the cathode circuit. This voltage is then applied to the metering circuit resulting in a significant decrease in DC voltage caused by voltage drops that occur in the meter "multiplier" resistors, reducing the voltage down to the "mv" level, that is then applied to the meter through the "IP" meter switch setting. The metering circuit in the 520, 820, 530, and 830 hybrids measures "voltage" even though the meter's top scale is registering "current".

The Rectifier Unit board shown in the eBay add is not from a TS-820 but rather from a TS-830. None of the resistors on the TS-830 Rectifier Unit board pictured in the eBay ad show any signs of being "toast" (overheated) so that is not what's wrong with the Rectifier Unit board.

Mike W5RKL

On 12/13/2013 10:56 AM, Michael Sylvester wrote:

The 470 Ohm resistor on the rectifier board is usually toast too.
I just bought another 820S Tuesday, making 5 total here!!!
I just bought the RF finals board, Rectifier board for 820S and a 430 LPF board, to get the small relays, hoping they match the relays in LA-1000 amps (I have 2 right now), one pristine and one beater I've restored), for $60 delivered.

The damage you will find on the finals board would be the (4) grid resistors, the 1/2 watt 20 Ohm that act as fuses. Don't "super size" them as Ken, K4EAA.com (http://www.k4eaa.com/examples.html) would say. He has a page showing what happens when you increase the wattage rating of resistors there to keep them from burning up. Can't find it right now...
Kenwood designed them to act as fuses protecting the other components.I just replaced (10), yes 10, 33 Ohm 1/4 watt resistors in parallel that replaced them on one radio, I think the "oldham" that went silent key must have bought them for bulk quantity price.......
The TS-530S I've nicknamed "Old Dog", looks like he went through WWI in the trenches. 10-33's in parallel make 3 Ohms, real high wattage, too high current, and is probably why he had fires on that board and the Rectifier board.
"Old Dog" is the the brother of "Pretty Sister", the pristine, perfect low miles TS-530S I had for sale on eBay, came from the same estate.
I've got 20 or so hours into "Old Dog" and not done yet.
The other damage you will find is R11 on the rectifier board. A 470 Ohm resistor. Had a fire there too......
I had a man contact me on eBay, try to give a bunch of knowledge but his letter was lost because it contained an email addy, eBay clips the emails.
He later contacted me by Personal email, found it on my QRZ page I'd geuss. He said he found by trial and error that the GE 6146W tubes are not biased right for Kenwood Transceivers, the hard way by burning up some boards using the GE W's.
I believe He's right and that they are the source of many fried Finals and Rectifier boards. I won't be using any. Sylvania 6146W seem to be ok however.

Subject: [TS-520_820_530_830] What's wrong with this board?

There's a TS-830S Rectifier Unit board being sold on eBay for $20 plus $5 shipping. The eBay ID number is 400622364893. Go to ebay.com, put that ID number in eBay's search box and click search and the ad will come up. I mean no disrespect towards the eBay seller who is selling the TS-830 Rectifier Unit board shown in that eBay add. However, can you find what's wrong with the board he is selling by simply looking at the component side picture in his ad?His ad says the 830 receiver worked fine but the transmitter had no output. He further says he found a bad resistor on the final board. He then said the Rectifier board was probably okay but there were no guarantees. The issue is not "there's no guarantees" statement. That's more often than not to be expected when selling used equipment.However, can you see what is wrong with the Rectifier Unit board he is selling and what could easily have been the source for the resistor failure on the final unit board he says in his description? Also, what other possible failures in the final amplifier/final unit board could have possibly occurred that he may not be aware of by looking at the Rectifier Unit board he is selling?73Mike W5RKL

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

Mike W5RKL

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has

gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered

do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

73
Mike W5RKL

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms,
R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either,

so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth

resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Emne: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Dave,

Yep you're right if you are referring to the large 2 watt resistor, color bands BLUE/GRAY/BLACK/SILVER indicating 68 ohms 10% tolerance, mounted just to the left of RL1 on the 830's Rectifier Unit board. That LARGE 68 ohm 2 watt resistor replaced the original design 470 ohm 1/2 watt for R11, a VERY VERY BAD idea!

That LARGE resistor should have stuck out like a sore thumb to anyone looking at the board. For example, the seller said the 830 had no RF output and he found a resistor on the Final board that was bad. If that Rectifier Unit board was found in an 830 with that large 68 ohm 2 watt resistor in place of the original 470 ohm 1/2 watt resistor for R11, I would instantly suspect there are more problems than one bad resistor on the Final Unit board. At a minimum, I would not trust the 6146Bs in the final amplifier, they could easily have been permanently damaged.

This should be a clear indicator for those members who may have considered doing this because they read or were told they can increase their TS-830's power output by changing R11 to a lower resistance value, that they should NOT do that!!!

The 6146B's ICAS service maximum ratings in Class AB1 RF amplifier are:

Maximum screen voltage (Grid #2) is 250VDC
Maximum screen power dissipation (Grid #2) is 3 watts which equals a maximum screen current (Grid #2) of 12ma (3 / 250 = .012).

ICAS stands for "Intermittent Commercial and Amateur Service"
CCS stands for "Continuous Commercial Service".

The other QRO mod and maybe more common one is to simply move the 210A lead over to the 300 terminal on the Rect Unit Board. Now you have increased the SG voltage to the Driver tube as well as the 6146 finals.

What is sad about this is it shows absolutely no understanding of what the effect of raising RF output power from 100 watts to 130 watts means on the receiving end. Remember it take 4X power increase to realize 1 S-unit increase.

Also none of these QRO mods consider what effect on IMD but who cares about linearity if you have this kind of mentality.

Some of you may remember that back in th 70s Jerry Ginsberg W6TOG (SK) sold mod kits for the TS520 and TS820 rigs. One popular kit was a QRO kit that included changing the S2001 tubes out for 6293 pulse rated tubes, raising the screen grid voltage as Mike discusses, changing the ALC time constant resistors and capacitors to shorten the recovery time so ALC provided some level of compression, and even changing the zero signal plate current bias voltage setting.

As hams we have been experimenting and modifying rigs since day one, but some of these mods are very ill conceived.

W6TOG was a smart guy and made money by selling KW hybrid owners kits that included different front end dual gate mosfets promising improved rx sensitivity and better noise figure, different balanced mixer devices that promised better RF overload immunity, and lastly his Magicom board that converts the TS-820 speech processor from a compressor to a rf clipper.

I have seen them all and in my opinion none produce the dramatic promised effects. At least not to my ear. When I find them in a customers rig I confer with the owner and recommend removal. Just recently had a TS-820 with the Magicom board hanging off back of IF board.

A properly aligned TS-820 speech processor works just fine.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices,

www.k4eaa.com .

Sorry for the mistakes.

Mike W5RKL

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal

noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke

and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

Mike W5RKL

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

(regarding the theorized possible damage fom GE 6146W tubes)

From: "Your hybrid wont know what 6146 is in the socket. Any and all will work just fine. Best to not mix no suffx or A and B as they have slightly different inter-electrode capacitance, but any brand other than the new Chinese will work just fine. No need for matched pairs as we are running parallel and not push pull.
Terry K9TW
,Quote:

I am sorry but this is starting to get pretty scary and a bit concerned for our newly licensed and first time KW hybrid owners that may be taking notes on this. "
Terry K9TW

Unquote.

Sorry, didn't mean to steer anyone wrong with buggered up information.
I too am a new ticket and first time Kenwood owner.

What is wrong with the Khainese tubes, in your opinion, other than country of origin?

Good to hear that unmatched tubes will work in the finals.

Never heard that before.
So then why do unmatched tubes blow so often for me? Matched tubes don't however so it's not that I'm an idiot or that I have no clue how to tune. I do know now that alot of that WAS a learning process and also from using cheap questionable used tubes
I have several Hybrids, some need work. So I've tried several radios and went through several mismatched sets of used tubes.

I too have a new ticket and never owned a Kenwood before 3 months ago.

I didn't mean to "scare" you.
Perhaps it would be better if I did not participate here, if never allowed to use a wrong word, or suggest a controversial idea, without being berated.
Surely you would rather not hear of my new ideas or techniques to clean wafer switches, new tools I've made just for that purpose. Or how I am repairing the wafer contacts using methods before untried, with good success. Certainly nobody could come up with a method better than spraying petroleum distilates all over our cirquit boards. Everything has been thought of and tried in the 35 year history of the Hybrids.
After all I am a "new ticket".

Perhaps it would be better for my ego to not come here to share my ideas to be pounced upon by even bigger egos for mistakes like using the word grid instead of cathode. I mispoke. I even checked the schematic before I wrote to get it right and still used the wrong term. Surely that mistake has never been made here before?

I have an extensive electronics background but have not used much of it in decades.
If I am not contributing in a beneficial way I'll keep my ideas to myself and keep my mouth

shut,
boy that would be hard.
I freely admit I'm human and make mistakes. More so as I get older.
I am, like alot of you, smarter than most. I've learned alot in my short time here, I am a very fast learner.
But my ego is fragile. Please be more tolerant of my errors and be more considerate of my ideas.
If we could all be a bit more tolerant and understanding, showing the patience and understanding we like to receive, we can all learn from one another.
Even from a new ticket.
Thanks for putting up with me, I know it can be hard.

Please answer my question regarding Khianese tubes.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Yes, I mispoke. I'm old, goofy, and ignorant.
The reference to the GE 6146W not being good in the Kenwoods is from another man that gave me alot of info yesterday. He said he burned up 3 or 4 boards using the GE W's and that his conclusion was something is not right with them in Kenwood transceivers. Obviously not bias, those were his words.

Again, from Kens' website:
Damaged Cathode Resistors
If a rig appears to load up properly, with sufficient plate current and good high voltage, but suffers from low output, the answer is many times the cathode resistors. Kenwood uses these resistors as fuses, to protect the finals and power transformer if the rig is mistuned for any length of time. The resistors will overheat, start to climb in resistance, and maybe even burn and rupture. In the picture below, the larger 1W 10 ohm resistors are in series with the cathodes of the 6146B's. In a rig that's been abused, these resistors may look fine, but actually be high in value from being overheated. The only way to tell is to measure them. Being in parallel, they should measure a total 5 ohms to ground. The plate current metering is derived from these R's, and will read much higher than it's actual value if the resistors are damaged. I replace them with 10 ohm 1W metal film units, to maintain the safety that they provide as pseudo-fuses.

I suggest you also go debate the fuse theory with your freind Ken. I'm sure he knows what the difference between grid and Cathode resistors is however and will not mispeak.
Pardon my mispoken tube part name. Forgive my ignorance, I've been away for a bit.
Man, tough croud today.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael:

With all due respect:

1. "Grid Resistors"???

Do you mean Cathode meter shunt resistors? Or are you talking about the SG grid stopper resistors?

Are the cathode meter shunt resistors in a Yaesu FT-101, Heath HW-101, or Drake T4X "fuses" as well? Are they designed to blow to protect "other components" ? Wonder how often they blow?

Ken Kempski is a smart man and a friend but I do not want my cathode resistors blowing open. I like to keep my panel meter. Take a read on KW hybrid cathode resistor topic on W8JI Tom Rauch website.

2. "GE 6146W tubes are not biased right for Kenwood Transceivers"???

What does this mean as no vacuum tube comes "biased"? Please elaborate.

Your hybrid wont know what 6146 is in the socket. Any and all will work just fine. Best to not mix no suffx or A and B as they have slightly different inter-electrode capacitance, but any brand other than the new Chinese will work just fine. No need for matched pairs as we are running parallel and not push pull.

I am sorry but this is starting to get pretty scary and a bit concerned for our newly licensed and first time KW hybrid owners that may be taking notes on this.

Michael

I dont know you. I dont know your formal education level. I dont know your fundamental electronic knowledge. I dont know your fundamental radio theory knowledge, I do not know your KW hybrid knowledge or experience.

There is nothing wrong with being new. We all were at one time. However, a new person who listens and asks is far more likely to be taken seriously than one who speaks when clearly has little or no knowledge of the subject.

All I or anyone else on this forum can go by is what you say and how you say it in writing. After about 3 or 4 posts and responses a picture is painted. The perception may be wrong, but important for you to know what that perception is and to care about it and to take action to change it if it is wrong. Perception is always the other guys reality.

Regarding perception it is clear you have lots of zeal and are anxious to help, but it is also very obvious that you lack basic electronic knowledge, vacuum tube fundamentals, and KW hybrid knowledge and experience OR you have become very very rusty. Time will tell.

One of the very worst things any of us can do on this forum is bum dope people. Any and all of us should be corrected when we give out bad or just plain wrong technical advice. We are adults and should not take that as personal attack. Sometimes we just make a mistake or typo and other times we are out in left field. That includes me.

There will always be professional differences of opinion but those should be debated on the merits of the technical basis that each side presents and not on subjective or anecdotal or tribal myths and beliefs. Far too much of that abounds on the various ham radio forums today. For example, you will always have those who insist that matched pair finals are better or necessary and when quizzed about only one bias voltage pot and no ability to individually set the zero signal plate current they huff and puff and tap dance around.

You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea. Many people recommend cleaning molex connectors as first step in resolving any and all operational issues with a hybrid. I am in the camp that this is silly and bad advice. It represents risk of immediate damage and introducing latent failure and simply is not required. Yes from time to time it will resolve an issue, but what really fixed the problem? Experiential based troubleshooting is fine, but once that is exhausted have to break out the schematic and test gear. Also, Corrosion X is commonly used by the RC model boat folks who routinely immerse their electronics. I never submerge any of my KW hybrids. Deoxit and Fader lube properly applied works great and no oily smelly greasy residue. By the way a TS-520 has no molex connectors as it uses wire wrap terminal posts.

So I appreciate your zeal and interest and eagerness to help, but it appears to me at this stage of your development you would be better served reading the post, asking questions, and learning. However, it is your call if you wish to continue responding as you have been. You need to earn respect and that will come with the quality of your questions and

responses.

I am not telling you that you are not welcome on this forum. I am not the owner and not in position to say one way or another. What I can offer is if you want to learn there are people here with 40 to 50 years ham radio knowledge and experience who grew up in the tube era and who have 10 to 15 years of hands on KW hybrid repair and they freely share any and all of their knowledge and experience. Up to you if you want to avail yourself of that valuable resource. Of course as we age we are looking for new folks to take our place holding up the tent poles. Those people dont get produced over night.

Just dont be too thin skinned or have fragile self esteem. When someone corrects you it is meant to help you and every new person who is following along. This is a technical forum and a KW hybrid is a complex engineering marvel. To be taken seriously you need to be credible.

"Reburbing" KW hybrids by cleaning, lubing, and painting them does not make anyone a KW hybrid service tech. Yes cosmetic cleaning is a part of repair, but it takes knowledge, experience, proper test gear, and knowing how to use it to run the Service Manual steps to restore a KW hybrid to factory performance level. Sure you can run the Owner Instruction Manual Maintenance section steps and get rig in pretty good shape. It just depends on how many golden screw drivers have been inside the rig and what your definition of performance and quality is.

Any technical discipline comes with its own parlance and jargon and using the terminology in the proper context speaks volumes about the persons knowledge and experience level.

So sorry if I hurt your feelings, but very hard to sit on sidelines and read advice that the goes way beyond not using the parlance properly. So to be 100% honest with you in my mind the jury is still out. Hopefully, you care enough to accept the challenge and prove me and others wrong.

Hi Bill,

The following link will allow you to download the manual for the Swam 1200W amp which has the required changes in the manual under the "Installation" section.

http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=2&cad=rja&ved=0CC8QFjAB&url=http%3A%2F%2Fgmcotton.com%2FHam_Radio%2FMISC%2520Manuals%2FSwan%2FSwan_1200W%2520Linear_Service%2520Manual.pdf&ei=tdesUsCUB-mc2QXho4HQCQ&usg=AFQjCNGF5osQRQ5y6qO2E_WeE2k1XbhuQw&bvm=bv.57967247,d.b2I

You should know the Swan 1200 amplifier does not have an internal cooling fan to blow air across the tubes. The amplifier uses "6LQ6" sweep tubes, four of them. You must follow the instructions for tune up and operating so you do not over drive the amplifier and/or overheat the tubes. Before you make any changes to the amplifier's relay switching circuit, you should check the amplifier first, it's quite possible a previous owner may have made the changes outlined in the amplifier's manual. You should also check for a fan that may have been installed by a previous owner, the amplifier did not have an internal fan when it came from the factory. If there is no fan you should seriously consider installing one that blows air at the tubes. Those sweep tubes are not cheap and can easily be damaged by excessive heat.

To Terry K9TW ,
Thank you for your kind and considerate advice.
Wise words.
You said that I mentioned I'm cleaning the molex connectors, I don't know what a molex connector is. I could have looked it up and not admitted my ignorance.
"a TS-520 has no molex connectors as it uses wire wrap terminal posts."

What I'm doing is cleaning all the multiple wire plugs that are everywhere.
Coating them, gently wire brushing them then pushing and pulling the plugs on and off 3 times.
Cleaned and coated.
Mechanical connections are one of the biggest problem sources of these antique rigs, in my estimation.

With the wafer switches I'm making custom brushes, some just for particular switches, to gently rub the tarnish off the rotating discs, after spraying, cleaning and coating.
I'm trying Corrosion X after hearing a few Hams swear by that, others swear by Deoxit, I've bought them all and will try them all and draw my own conclusions, hopefully I'll live long enough to see the differences.
I will be trying the Fader Lube now because you endorse it and seem knowledgable. Ken likes it too, good enough for you guys I'll at least try it.

I'm using small artists paint brushes to apply chems to just the areas I want coated. I don't like the idea of just bathing or spraying down an area with volumes of toxic, expensive chemicals. I know it can and does work to an extent.

There are some Hams that "dip" or soak boards in chems.....with good results. I've read of using the dishwasher. I'm thinking of gently using the carwash on one I have that is filthy and letting it dry out for days near my woodburner.....
(I recall spraying tuners in the old tv's back in the day.)

(Still not sure what the molex are.)

The man that insisted (by email) the the GE 6146W has PROVEN to him they don't work real well in Kenwood transceivers was very adamant that he'd blown RF boards and Rectifier boards only when he'd used those tubes. He has done the repeated trial and error expensive test, in more than one radio.
For now I'll take his word for it and use other tubes.
Ok, it's not a bias difference (wrong terminology, yes, but HIS words), perhaps internal capacitance differences or I don't know what.
Biasing requirements of the tubes?

I'm surprised that there is such a divide on the opinion of the grid resistors being "pseudo fuses" or not. I understand they establish meter current levels acting as shunts in the cirquit.
(The cobwebs are slowly coming off my electronics memories.)
My impression of K4EAA was that he was one of the "gurus" and his statements were accepted

Biblical truths. I geuss not!!!

So, long story short, Thanks Terry for GENTLY stating your position.
Also for tolerating an ignorant egotistical mechanical genius that doesn't know squat about Kenwoods.....
I will do my best in future to more specifically select my wording when writing of a technical nature and will try to not impress so needfully to gratify my ego.
!!!!??
I appreciate you guys putting up with me,
so far!.....I'll attempt to not be so annoying in future (good luck with that) and to commit fewer errors to words here!

Answer for me, what is your objection to the Khainese tubes, other than country of origin? I've bought one set, I think that was the pair that one slipped out of my hand and I cracked the glass. I haven't had a set long enough to establish an opinion.

Second, explain Molex connector to me. You said:
"You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea."

What I think might be a new idea (I'm sure somebody has done it before) is using tiny brushes to remove even more tarnish off the rotating discs of the wafer switches that Deoxit spray didn't. While avoiding touching or damaging the fingers of the springy contacts. I really like the idea.
I seem to be having good success with rigs that are giving trouble from bad connections in this switching area.
Some discs are black with corrosion even after spraying, when I'm done most look like new.
The HV cage presents special challenges since it's so crowded. I'm making brushes for each area that are different as I find a way to get at them, away from the delicate contacts.

Also, what is your personal opinion of the apparent difference of opinion on whether the Cathode? resistors act as "pseudo fuses" as Ken calls them?

I'm running about 40 hours now on 2 hours sleep last night. Been doing that alot lately, pushing and testing myself mentally and physically, on purpose.
While it helps me to understand my limits and capabilities, it also turns me into a short tempered, dimwit a**hole, that's offended easily.

I'm expecting great turmoil in our country soon. I need to know my limits and also know I can "operate" under duress and for long hours.
I hope I'm wrong regarding the turmoil.

I pray I'm wrong.

In summation, answer about the Khainese tubes?
What are Molex connectors?
Your opinion on the "fuses" debate please.

Thank you for your time and patience Terry.

"Communications will be key"
Michael///KD0WSJ

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael

I dont know you. I dont know your formal education level. I dont know your fundamental electronic knowledge. I dont know your fundamental radio theory knowledge, I do not know your KW hybrid knowledge or experience.

There is nothing wrong with being new. We all were at one time. However, a new person who listens and asks is far more likely to be taken seriously than one who speaks when clearly has little or no knowledge of the subject.

All I or anyone else on this forum can go by is what you say and how you say it in writing. After about 3 or 4 posts and responses a picture is painted. The perception may be wrong, but important for you to know what that perception is and to care about it and to take action to change it if it is wrong. Perception is always the other guys reality.

Regarding perception it is clear you have lots of zeal and are anxious to help, but it is also very obvious that you lack basic electronic knowledge, vacuum tube fundamentals, and KW hybrid knowledge and experience OR you have become very very rusty. Time will tell.

One of the very worst things any of us can do on this forum is bum dope people. Any and all of us should be corrected when we give out bad or just plain wrong technical advice. We are adults and should not take that as personal attack. Sometimes we just make a mistake or typo and other times we are out in left field. That includes me.

There will always be professional differences of opinion but those should be debated on the merits of the technical basis that each side presents and not on subjective or anecdotal or tribal myths and beliefs. Far too much of that abounds on the various ham radio forums today. For example, you will always have those who insist that matched pair finals are better or necessary and when quizzed about only one bias voltage pot and no ability to individually set the zero signal plate current they huff and puff and tap dance around.

You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea. Many people recommend cleaning molex connectors as first step in resolving any and all operational issues with a hybrid. I am in the camp that this is silly and bad advice. It represents risk of immediate damage and introducing latent failure and simply is not required. Yes from time to time it will resolve an issue, but what really fixed the problem? Experiential based troubleshooting is fine, but once that is exhausted have to break out the schematic and test gear. Also, Corrosion X is commonly used by the RC model boat folks who routinely immerse their electronics. I never submerge any of my KW hybrids. Deoxit and Fader lube properly applied works great and no oily smelly greasy residue. By the way a TS-520 has no molex connectors as it uses wire wrap terminal posts.

So I appreciate your zeal and interest and eagerness to help, but it appears to me at this stage of your development you would be better served reading the post, asking questions, and learning. However, it is your call if you wish to continue responding as you have been. You need to earn respect and that will come with the quality of your questions and

responses.

I am not telling you that you are not welcome on this forum. I am not the owner and not in position to say one way or another. What I can offer is if you want to learn there are people here with 40 to 50 years ham radio knowledge and experience who grew up in the tube era and who have 10 to 15 years of hands on KW hybrid repair and they freely share any and all of their knowledge and experience. Up to you if you want to avail yourself of that valuable resource. Of course as we age we are looking for new folks to take our place holding up the tent poles. Those people dont get produced over night.

Just dont be too thin skinned or have fragile self esteem. When someone corrects you it is meant to help you and every new person who is following along. This is a technical forum and a KW hybrid is a complex engineering marvel. To be taken seriously you need to be credible.

"Reburbing" KW hybrids by cleaning, lubing, and painting them does not make anyone a KW hybrid service tech. Yes cosmetic cleaning is a part of repair, but it takes knowledge, experience, proper test gear, and knowing how to use it to run the Service Manual steps to restore a KW hybrid to factory performance level. Sure you can run the Owner Instruction Manual Maintenance section steps and get rig in pretty good shape. It just depends on how many golden screw drivers have been inside the rig and what your definition of performance and quality is.

Any technical discipline comes with its own parlance and jargon and using the terminology in the proper context speaks volumes about the persons knowledge and experience level.

So sorry if I hurt your feelings, but very hard to sit on sidelines and read advice that the goes way beyond not using the parlance properly. So to be 100% honest with you in my mind the jury is still out. Hopefully, you care enough to accept the challenge and prove me and others wrong.

Terry K9TW

Being very careful to avoid the contact fingers, I know how delicate they are, I've repaired a few using Sterling Silver wire, magnifier lamp while wearing 2.25 glasses and fine tip soldering tools. Like doing microsurgery. Quite the challenge. I think it was about 22 gauge silver, I had to restore the springy touch of the contact and solder to it's tip, tough job.

Hi Brett,

When you have no power output in SSB, if you switch to CW will the rig transmit in CW?

A useful learning experience will be to study the block diagram of the rig and the transmitter description in the manual so that you know how the transmitted signal is generated.

Here is what I would do.

Tune up the rig when its working or if it works in CW.
Turn the SG (screen grid) switch on the back to the off position. This will save wear on the finals while troubleshooting. You won't get any power output in this position.
Connect an audio generator to the mic input and set it to something like 1kHz. Set the level to something like 10mV. I don't know the exact level you will need but I would think it would be enough. If you don't have one you can key the mic and whistle.
Set the mode to SSB.
Now you can key the rig (probably need to use a jumper on the PTT line if you use an audio gen).
Use a scope to check the various stages to see if signals are present.

If it works in CW but not in SSB the problem is probably in the mic audio amp stages. Set the VOX/MAN switch in MAN to eliminate the VOX circuits from having any influence.
I would check to see that you are getting audio output from the various mic audio stages.

73,

Bill

Subject: [TS-520_820_530_830] New to the group, having problems with SSB transmit TS520

Hi all, I'm new to the group, and a new Technician as well. I recently purchased a clean TS520. I did the DeOxit clean-up, got all the scratchiness out of the switches and potentiometers. The radio tunes up fine on 10 meters, and does right at 100 watts. The problem comes when transmitting on SSB. I can listen and hear my transmission through another monitor rig, and it sounds fine. The problem is the output is intermittent. I have tried two mics with the same outcome... no power output on SSB. Out of the blue, the power will come on strong, and I have gotten good audio reports when it is working right. I can hear the relay click when I key/unkey the mic. I have done extra cleaning of the mic gain/compressor/carrier potentiometers. The problem is still intermittent. Is there something else I should be looking at to fix the problem?

Brett,

One more thought. Does it fail to work in both USB and LSB or just one of them? I see on the block diagram that there are three xtals for the carrier gen. If it fails just one, its possible that the carrier osc xtal for that mode is having startup issues.

46415. High SWR into dummy load!

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-15 11:31:33 UTC
From: <adrian@...>
Topic: 46415 Message: 46415

I am having a baffling time with my TS520SE.

One step forward, 2 steps back as I had fixed problem of very low sensitivity on WWV receive by replacing blown Q5 2SK19.

Spent a day last weekend trying to troubleshoot problem with rig not tuning up on output (was getting high SWR and low Ip, which I finally traced to an open circuit patch lead which I was using to connect to dummy load!

So I had been operating the rig and trying to tune it with effectively no load on the output. I'm worried that this has caused some damage as I am now getting high SWR into dummy load, and incredibly high SWR into my usual antenna.

Here are symptoms. Tuning into an MFJ dummy load (which I am almost certain showed SWR close to 1.0 in past on Welz RF/SWR meter), I am seeing SWR of 1.4, 1.6, 2.5, 4.0 on 10m, 20m, 40m, 80m respectively. When I peak power I am seeing lower Ip then I would normally see (170mA when I would usually see around 200mA).

If I try to switch in my antenna (off centre fed dipole) then on the Welz meter I see far higher SWR than when rig was operating normally. On 40m say when I could tune SWR down to 1 using an AT130 matching unit, I now can't dip the SWR below the red portion on the meter, and the Welz meter shows an SWR of over 10!

I know it's not antenna system, as I am getting those high SWR figures into dummy load, but I can't figure out what would be problem in rig which would mean I would see high SWR into external dummy load? It must be something really simple but I'm baffled.

Where should I be looking to start testing/fixing? The receive side of the rig is working perfectly.

Thanks and 73, Adrian G4IQW

Minimise your variables.

Start by checking your patch leads, SWR meter and dummy load with a known-good radio. Fling the ATU for now, it's just going to mislead you.

If there are any questions over the reliability of the patch leads, dummy load, or SWR meter, get or make known-good ones.

With the dummy load connected to the radio, see if you can load it up as expected on all bands. Just the dummy load, a patch lead and the radio. Note down the meter readings you obtain on all bands. They will be slightly different on each band, but they should more-or-less match up with the handbook.

First things first, though - check the cables, SWR meter and dummy load. Then check them again.

I agree remove the tuner for this troubleshooting. If you need it for SWR bridge or wattmeter then see if you can borrow a bridge or wattmeter from someone. If not a bad patch cord then open the PA cage and inspect the bare tinned lead at center of SO-239. I have found them not soldered and will pull out with gentle tug. Also look at all the soldering to the tank cap and tank coil. Might even clean the TR relay contacts.

As to hurting your TS520SE by loading into an open I doubt it. Here is what happens: (the weak link is the close spacing of the Plate load cap)

With very high SWR the PA load line will shift. The load impedance RL presented to the 6146 finals is now very high. The PA is now under-coupled. This means there will be less RF current, but much higher RF voltage. Very high vswr causes higher PA rf voltage swing.

What is approx normal RF voltage across the tank capacitor and the plate load capacitor? Most folks cant measure it. I have high voltage P5100 scope probe and capacitive voltage divider for use with HP-410C so can measure it couple of ways. So I can tell you what "normal" is. It can also be calculated. Approx calcs are as follows:

RF rms tank cap volts = 6146 Plate dc voltage x .9 x .707 or 850vdc x .9 x .707 = 541 rf volts across C1.

RF volts across 50 ohm dummy load at 100 watts is E squared = P x R or
100 x 50 = 5000. Square root of 5000 = 70.7 rf volts . Approx 71 volts is across the Plate Load cap C2.

These are approx voltages at 1:1 SWR.

If you load into an open you have very high input impedance. With very high Z there will be very high voltage. The weak links are the Plate Load capacitor and the bandswitch contacts. The Plate Load cap has very close spacing (almost broadcast band receiver spacing). As noted it is the weakest link.

One of the problems with using the old dip and load method to load a hybrid is the plate current will fool you into thinking all is well unless you are experienced at recognizing there is an issue. Also the RF meter position will register and indicate as it is measuring the RF voltage at the SO-239. It will register much higher than normal. An external wattmeter will tell you immediately that you have a problem as you will have no RF output or it will intermittent.

I dont recommend that a new person try this but I have loaded all the hybrids with no load connected and measured the rf voltages across the Tank cap and Load cap. Here is measured values for a TS-520 with no load connected and 100ma plate current. .

RF voltage across Plate Load cap = 200 rms rf volts. This is almost 3 times normal 70.7 rf volts that would have with 50 ohm dummy load connected and loaded to 200 ma.

I did not load any higher as I did not want to arc over the Plate Loading cap. It is the weak link. Not easy to repair arced over plates back to original.

On a TS820 or TS830 that employ RF negative feedback the voltage will be approx 100 rms rf volts. Wont go into explanation of how RF negative feedback works. Just know it is harder to hurt these models with open antenna.

So point of all of this is I would not be too worried that you hurt your TS520 by loading it into an open. More than likely you would have heard and seen the effects of the plates of the loading cap arcing over and as you now attempt to load when you would reach that same amount of plate mesh would likely arc over again at that same spot as metal has been raised at that spot and you will see that on the plate current and wattmeter as it makes frying or arcing noise.

The voltage across the Tank cap does increase as well but not to extremes and it has much larger plate spacing so not as likely for it to arc over during an open load event.

Topic: 46351 Message: 46418

Michael

You have covered a lot of ground here. Will attempt to address it all. If not we can take this off list or start new post?

1. Use of Artist brushes very good idea. I try not to spray anything as hard to control amount and really direct it and to clean off all the residue.

2. OK to try different contact cleaners. Everyone has there favorite. Fader lube is good for carbon trace pots. Usual weak link is the rivet to pc trace interface and not the actual contact fingers unless someone has been in there and pressed on them. They are phosphor bronze with spring temper and can take thousands of spread cycles.Never attempt screwdriver to close them. Only way to change that gap is perhaps attempt a twist. Best to measure contact resistance by applying approx 6 vdc and 1 amp and measuring the millivolt drop across the contacts. Ohm meter test is not good way to find bad contact as no current is used.

3. Molex connector is the brand name. The large white connectors on the TS820 are Molex connectors. Just much heavier. A smaller version is used on the TS530 and TS830. You havent lived until you pull 5 or 6 off a board. The pins and sockets in the two connectors are plated and should last long time, but cleaning with contact cleaners and wiping them by multiple cycling can help, but it comes with some risk especially on the TS530 and TS830. I always inspect the connector body pins on foil side of the boards under magnification when board is removed. I insert a plug back on the connector and gently rock back and forth and observe and not uncommon to see a complete 360 degree circumferential crack around the pin and solder "cone".. The pin is floating and can see it moving. In some cases the solder never wetted to the pin. The pin has now developed oxide coating and you cannot simply resolder it. Need to remove the old solder and clean the pin and resolder.

Other problem with repeated cleaning and plug and unplug cycles of these molex connectors is you can rock the connector body and induce a crack in the foil trace right at the pin pad junction. That crack is hard to see due to the solder mask and it can cause you fits.

So with 30 to 40 year old radios best not to fix things that are not broken.

I have had TS820 rigs here where owner broke corner off RF board trying to remove Molex connector and broke the FIX board trying to remove a seized molex connector. Just have to be damn careful.

4. Chinese tubes. They have a bad reputation for arc over. I have never run them but do find them in customers rigs. Have had opportunity to dc hi-pot them. Your 6146 finals see approx 1600 rf volts swing so need to be able to hold off that level. I have DC hi-pot and test a lot of 6146 finals. Good RCA and Sylvania will usually hold off 2000 to 2500 volts. I have tested couple of sets of Chinese and one arced over at 1100 and the other at 1500. So I dont have a lot of experience with them. They just do not have a good reputation. Maybe they are getting better?

5. I wont go into a long debate over cathode resistors designed as fuses in detail here as it has been discussed numerous times on this forum. You can search the forum and find all of the previous debate. It is one area where Ken and I agree to disagree. Briefly:

A. When 6146 tubes go into thermal runaway due to loss of operating bias and plates are glowing cherry red why dont the cathode resistor blow open? Run your bias voltage down and watch what happens (I dont really recommend this).

B. Carbon resistors can stand extreme over current and wattage dissipation for a very long time. Have you ever connected DC supply or Variac to a carbon resistor on your bench and run the current up? You can get them to start smoking and eventually glowing so that you literally see color in them. They wont pop open under those conditions. I would not want enough plate current to flow in my PA to cause the cathode resistors to glow. What would they be protecting then?

C. When is last time you blew a cathode resistor open on your HW-101, or SB-102, or Drake T4X or any other 6146 boat anchor transmitter? They all typically measure plate current the same way. Seldom see any post or discussion about cathode resistors popping open on these other forums.

D. Only way to experience an instantaneous cathode resistor failure is to have a 6146 anode to cathode arc over. 900 vdc / 5 ohms = 180 amps. (not considering the power supply esr that would add some additional current limiting during the fault). This did not happen back in the KW hybrid heyday with brand new S2001 or 6146B tubes. It is only a more recent phenomenon due to 35 to 40 year old NOS and pulls available that have off gassed and/or have some ingress around tube pin seals after all these years.

E. Lastly you never want your cathode to become open circuited. As I previously mentioned in other response. When tube arcs over and momentarily have 160 amps fault current flowing thru 5 ohms then the IR drop is approx 800vdc. The maximum voltage your panel meter can stand is approx 0.40vdc (it is a ua meter movement). A 0,4 vdc meter isnt going to like it when it now tries to measure 800vdc!. If it survives the initial fault now you have an open cathode and it will rise quickly toward Screen grid voltage. The only thing limiting it is the operating bias voltage. It will rise to over 100 vdc (I have measured it). When you place the meter to IP during attempt to reload after you hear that pop the meter will be stressed again.

Kenwood engineers would never fuse the cathode to save "other components" at risk of sacrificing the plate meter. Meter is far more delicate and expensive component.

Suggest you figure this out for yourself. Put four 20 ohm carbon resistors in parallel on your service bench and load them up and find out what it takes to get them to "fuse". You are going to see smoke and color before that happens.

If I failed to answer one of your questions let me know.

Terry K9TW

Thanks Gordon for good advice.

I moved the whole lot from dummy load back to rig to my vhf rig. It showed expected 1:1 swr and power reading so I can be sure that set of patch leads and dummy load and antenna switch is fine. Now will focus on 520SE.

In fact had bought new patch leads this week after cheap one failed on me last week, and I checked all these too for open/shorts and they are fine.

Thanks again Adrian G4IQW

Hello All
Now I have run into a slight problem with an 520-SE.
If I run the rig without processor, it sounds normal on lets say 1 a'clock on mod knob, but, when I turn on processor, the modulation jumps way to high, (comparing with my own 520) in order to make it sound normal, I have to turn knob down to about 9 a'clock... and if I then turn processor of, modulation is really low, and needs to be turned back up.
So Q is, is there an internal adjustment on processor gain?
Lars KB3WBT

By "mod" knob I assume you mean Mic gain pot? Was it working and has now changed or is rig new to you and just discovered not working correctly? May just need alignment. Would try that first.

Do you have the Service manual? Need to perform Step 19.

Requires Audio Generator and AF VTVM to accurately measure millivolt levels. Easy adjustment if you have the test gear.

Absent test gear may be able to find a audio generator app on the internet that uses output from your sound card.

Thanks Terry and you had the right diagnosis but in the wrong piece of gear!

I opened up PA cage and all was ok. No visible damage to plate cap either.

I discovered the high swr only happened when the Welz power meter in line with antenna/load. When I opened it up couldn't see a problem. But when I took off plate covering the in/out sockets then it was obvious that the copper wire wound round ferrite ring connected to antenna socket was blackened and melted! So that high RF voltage you mentioned with no load must have been "seen" by this choke. The wire is relatively thin. I remember the bad open circuit patch I found last week was connected between the power meter and dummy load.

The meter looked ok when I tested it on my FT221 2m rig as the problem lessened as frequency rose (my swr was worst on 40m and almost normal on 10m). At 144MHz that burnt up choke was not causing much of a problem. Unfortunately I didn't have another hf rig to compare with the TS520SE.

So all fixed now, but I need a new swr/power meter. Almost got an AT230 at good price on ebay last week. Will keep a watch for one as nice match to rig, and probably beefier than the melted Welz!

Thanks Terry and Gordon for pointing me in right direction to fix this.

No, you need to repair your SWR meter ;-)

Frank,

  If you look at the schematic of the 520 AND the 530/830, you will see that they run off the 100V tap on the transformer. The motors are I believe, wound for 120V...but the lower 100V
has them spinning a bit slower/quieter. I can not remember IF the fan mounting holes have the same dimensions regarding the mounting holes..but as stated earlier...they use the SAME voltage

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael

You have covered a lot of ground here. Will attempt to address it all. If not we can take this off list or start new post?

1. Use of Artist brushes very good idea. I try not to spray anything as hard to control amount and really direct it and to clean off all the residue.

2. OK to try different contact cleaners. Everyone has there favorite. Fader lube is good for carbon trace pots. Usual weak link is the rivet to pc trace interface and not the actual contact fingers unless someone has been in there and pressed on them. They are phosphor bronze with spring temper and can take thousands of spread cycles.Never attempt screwdriver to close them. Only way to change that gap is perhaps attempt a twist. Best to measure contact resistance by applying approx 6 vdc and 1 amp and measuring the millivolt drop across the contacts. Ohm meter test is not good way to find bad contact as no current is used.

3. Molex connector is the brand name. The large white connectors on the TS820 are Molex connectors. Just much heavier. A smaller version is used on the TS530 and TS830. You havent lived until you pull 5 or 6 off a board. The pins and sockets in the two connectors are plated and should last long time, but cleaning with contact cleaners and wiping them by multiple cycling can help, but it comes with some risk especially on the TS530 and TS830. I always inspect the connector body pins on foil side of the boards under magnification when board is removed. I insert a plug back on the connector and gently rock back and forth and observe and not uncommon to see a complete 360 degree circumferential crack around the pin and solder "cone".. The pin is floating and can see it moving. In some cases the solder never wetted to the pin. The pin has now developed oxide coating and you cannot simply

resolder it. Need to remove the old solder and clean the pin and resolder.

Other problem with repeated cleaning and plug and unplug cycles of these molex connectors is you can rock the connector body and induce a crack in the foil trace right at the pin pad junction. That crack is hard to see due to the solder mask and it can cause you fits.

So with 30 to 40 year old radios best not to fix things that are not broken.

I have had TS820 rigs here where owner broke corner off RF board trying to remove Molex connector and broke the FIX board trying to remove a seized molex connector. Just have to be damn careful.

4. Chinese tubes. They have a bad reputation for arc over. I have never run them but do find them in customers rigs. Have had opportunity to dc hi-pot them. Your 6146 finals see approx 1600 rf volts swing so need to be able to hold off that level. I have DC hi-pot and test a lot of 6146 finals. Good RCA and Sylvania will usually hold off 2000 to 2500 volts. I have tested couple of sets of Chinese and one arced over at 1100 and the other at 1500. So I dont have a lot of experience with them. They just do not have a good reputation. Maybe they are getting better?

5. I wont go into a long debate over cathode resistors designed as fuses in detail here as it has been discussed numerous times on this forum. You can search the forum and find all of the previous debate. It is one area where Ken and I agree to disagree. Briefly:

A. When 6146 tubes go into thermal runaway due to loss of operating bias and plates are glowing cherry red why dont the cathode resistor blow open? Run your bias voltage down and watch what happens (I dont really recommend this).

B. Carbon resistors can stand extreme over current and wattage dissipation for a very long time. Have you ever connected DC supply or Variac to a carbon resistor on your bench and run the current up? You can get them to start smoking and eventually glowing so that you literally see color in them. They wont pop open under those conditions. I would not want enough plate current to flow in my PA to cause the cathode resistors to glow. What would they be protecting then?

C. When is last time you blew a cathode resistor open on your HW-101, or SB-102, or Drake T4X or any other 6146 boat anchor transmitter? They all typically measure plate current the same way. Seldom see any post or discussion about cathode resistors popping open on these other forums.

D. Only way to experience an instantaneous cathode resistor failure is to have a 6146 anode to cathode arc over. 900 vdc / 5 ohms = 180 amps. (not considering the power supply esr that would add some additional current limiting during the fault). This did not happen back in the KW hybrid heyday with brand new S2001 or 6146B tubes. It is only a more recent phenomenon due to 35 to 40 year old NOS and pulls available that have off gassed and/or have some ingress around tube pin seals after all these years.

E. Lastly you never want your cathode to become open circuited. As I previously mentioned in other response. When tube arcs over and momentarily have 160 amps fault current flowing thru 5 ohms then the IR drop is approx 800vdc. The maximum voltage your panel meter can stand is approx 0.40vdc (it is a ua meter movement). A 0,4 vdc meter isnt going to like it when it now tries to measure 800vdc!. If it survives the initial fault now you have an open cathode and it will rise quickly toward Screen grid voltage. The only thing limiting it is

the operating bias voltage. It will rise to over 100 vdc (I have measured it). When you place the meter to IP during attempt to reload after you hear that pop the meter will be stressed again.

Kenwood engineers would never fuse the cathode to save "other components" at risk of sacrificing the plate meter. Meter is far more delicate and expensive component.

Suggest you figure this out for yourself. Put four 20 ohm carbon resistors in parallel on your service bench and load them up and find out what it takes to get them to "fuse". You are going to see smoke and color before that happens.

If I failed to answer one of your questions let me know.

46429. Kenwood Hybrid Net Update (December 15, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-15 21:08:20 UTC
From: Mark Gilger
Topic: 46429 Message: 46429

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net on 40 meters had 14 check ins under good band condition. There were 1 new check ins, KC8SIG. We had the following number of radios checking in.

3 running TS-520(x)
2 running TS-530(x)
3 running TS-820(x)
2 running TS-830S

I was using my TS-830s.

The Sunday□s 20 meter net had 21 stations checking in under good band conditions. There were 3 new stations checking in, KA1LQE, N5DHB, and W7JJH

Out of those, there was:

3 running TS-520(x)
4 running TS-530(x)
4 running TS-820(x)
2 running TS-830S

I was running my 820 twins, TS-820s + R-820.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit

and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 37, Sunday☐s total = 41 (Month to date)

Net Info:

If you are talking about a Ferrite core with melted winding you should inspect it after removing the winding to make sure not cracked. Also, pay attention to the wire as you remove it as it may be bifiliar wound.

Do you know the history of this wattmeter? Sounds like it has been used at power level beyond its rating?

Michael and Terry,

If I may add something to Terry's response.

Michael, you can easily calculate the approximately power dissipated in each cathode resistor in any of the KW TS-520, TS-820, TS-530, and TS-830 by simply performing simple math calculations using the following formula:

P = Isqrd x R

Let's assume an operator has improperly tuned their TS-520 resulting in 275ma of IP current.

We know that each cathode resistor is approximately 10 ohm 1 watt and the cathode current is 275ma so all we do is use these values and the above formula which will result in approximately .756 watts dissipated in each cathode resistor:

.275 x .275 = .075625 x 10 = .756 watts

Now lets increase the IP meter indication to 350ma, a much higher improper tuning IP cathode current in the final amplifier. What will the power dissipation in each cathode resistor be? Use the new 350ma IP current value, same 10 ohms 1 watt cathode resistor, and the same formula which results in approximately 1.225 watts dissipated in each cathode resistors:

.350 x .350 = .1225 x 10 = 1.225 watts

The additional .225 watts over the 1 watt power rating of each cathode resistor will not result in either of the cathode resistors to blow like a fuse.

You can also calculate the approximately cathode voltage using any value of IP cathode current by simply using the formula:

E = I x R

where "E" is the "unknown" cathode voltage, "I" is the value of IP cathode current, and R is the approximate 5 ohms of cathode resistance.

For example, if the IP cathode current is "60ma", what will the cathode voltage be and what will the power dissipated in each 10 ohm cathode resistor be? The cathode voltage will be approximately "+.3VDC" or "+300mv":

.06 x 5 = .3

The approximate power dissipated in each cathode resistor will be .036 watts or 36mw

.06 x .06 = .0036 x 10 = .036

This same math calculations can be performed on the TS-530 and TS-830 in the same way, using the same formulas.

Ron,
The freq. and times are listed at the bottom of the original email.
Thanks,
Mark

Hi Bill, (and others) for your response. Sorry it took me so long to get back on here. My "shack" is a shed in my back yard, and it does not have heat. Temps have been in the mid to low 20's here at night, and low 30's in the day, so I haven't spent a lot of time fiddling with the rig. Finally got warm today, and I played some more. I figured out that it is the potentiometer for the mic gain/carrier. It wiggles a tiny bit, and when you wiggle it, transmit comes back in. I need to figure out if I can tighten it, or if it needs to be replaced. Other than that, it seems to be working FB. 10 Meters contest this weekend, so no real chance to get a good audio report unless you like, 5/9 all the time. :)

Thanks again... this group is very active, and I'm impressed to have received responses so quickly!

73,
Brett

My first question too.
Read the entire post, it's at bottom of page, missed it this week.
I'd bet it's also listed at their website.

The wattmeter was fine up till incident I had last week with open circuit patch lead. I was seeing forward power pegging meter on that wattmeter (200W full scale) so suspect winding was damaged then. I dont know history as was used ebay purchase but prior to power and swr problems caused by faulty patch lead it has not given problem.

Thanks Mike

I have seen people who talk about blowing cathode resistors during mis-tuning events and as your math shows it just wont happen. For a couple of reasons. 1. Very hard if not impossible to ever see 350ma plate current on typical KW hybrid unless you are in thermal runaway and that is not due to mis-tuning and 2. The resistors can run all day long (essentially indefinitely) on that slight amount of additional dissipation over nameplate rating.

It seems like we have been here over and over again. I think it will be one of those things that people have strong beliefs whether the math and science supports it or not. Kind of like overheating and damaging the final tubes due to "high" SWR.

Probably should just avoid responding to any future pronouncements about cathode meter shunt resistors. Will save us all a lot of repeat key strokes. I need the discipline to do just that.

Maybe some day make a video of cathode resistor smoking and a shot of the current meter that shows what % overload it takes to do that. Better yet glowing like Christmas tree lamp!

Terry K9TW

To:
Mike W5RKL

I need you to clarify, since the cathode resistors are 20 ohms X 4.
You say 10 ohms. Are you looking at pairs as 2 separate cirquits?
2-20 ohm resistors in parralel per tube for the 10 ohms you speak of?

Since the tubes are in effect in parralel? Do the tubes each see 5 ohms or do the tubes eachsee 10 ohms?
I think they each see 5 since the metering is measuring their total combined cathode currents.
Then you mention the 5 ohm resultant resistance of 4-20's in parralel?
You are somewhat muddling the issue.
Clarify please.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael and Terry,

If I may add something to Terry's response.

Michael, you can easily calculate the approximately power dissipated in each cathode resistor in any of the KW TS-520, TS-820, TS-530, and TS-830 by simply performing simple math calculations using the following formula:

P = Isqrd x R

Let's assume an operator has improperly tuned their TS-520 resulting in 275ma of IP current.

We know that each cathode resistor is approximately 10 ohm 1 watt and the cathode current is 275ma so all we do is use these values and the above formula which will result in approximately .756 watts dissipated in each cathode resistor:

.275 x .275 = .075625 x 10 = .756 watts

Now lets increase the IP meter indication to 350ma, a much higher improper tuning IP cathode current in the final amplifier. What will the power dissipation in each cathode resistor be? Use the new 350ma IP current value, same 10 ohms 1 watt cathode resistor, and the same formula which results in approximately 1.225 watts dissipated in each cathode resistors:

.350 x .350 = .1225 x 10 = 1.225 watts

The additional .225 watts over the 1 watt power rating of each cathode resistor will not result in either of the cathode resistors to blow like a fuse.

You can also calculate the approximately cathode voltage using any value of IP cathode current by simply using the formula:

E = I x R

where "E" is the "unknown" cathode voltage, "I" is the value of IP cathode current, and R is the approximate 5 ohms of cathode resistance.

For example, if the IP cathode current is "60ma", what will the cathode voltage be and what will the power dissipated in each 10 ohm cathode resistor be? The cathode voltage will be approximately "+.3VDC" or "+300mv":

.06 x 5 = .3

The approximate power dissipated in each cathode resistor will be .036 watts or 36mw

.06 x .06 = .0036 x 10 = .036

This same math calculations can be performed on the TS-530 and TS-830 in the same way, using the same formulas.

>2. OK to try different contact cleaners. Everyone has there favorite. Fader lube is good for carbon trace pots. Usual weak link is the rivet to pc trace interface and not the actual contact fingers unless someone has been in there and pressed on them. They are phosphor bronze with spring temper and can take thousands of spread cycles.Never attempt screwdriver to close them. Only way to change that gap is perhaps attempt a twist. Best to measure contact resistance by applying approx 6 vdc and 1 amp and measuring the millivolt drop across the contacts. Ohm meter test is not good way to find bad contact as no current is used.
>
>
>3. Molex connector is the brand name. The large white connectors on the TS820 are Molex connectors. Just much heavier. A smaller version is used on the TS530 and TS830. You havent lived until you pull 5 or 6 off a board. The pins and sockets in the two connectors are plated and should last long time, but cleaning with contact cleaners and wiping them by multiple cycling can help, but it comes with some risk especially on the TS530 and TS830. I always inspect the connector body pins on foil side of the boards under magnification when board is removed. I insert a plug back on the connector and gently rock back and forth and observe and not uncommon to see a complete 360 degree circumferential crack around the pin and solder "cone".. The pin is floating and can see it moving. In some cases the solder never wetted to the pin. The pin has now developed oxide coating and you cannot simply resolder it. Need to remove the old solder and clean the pin and
resolder.
>
>
>Other problem with repeated cleaning and plug and unplug cycles of these molex connectors is you can rock the connector body and induce a crack in the foil trace right at the pin pad junction. That crack is hard to see due to the solder mask and it can cause you fits.
>

>I have had TS820 rigs here where owner broke corner off RF board trying to remove Molex connector and broke the FIX board trying to remove a seized molex connector. Just have to be damn careful.
>

>
>4. Chinese tubes. They have a bad reputation for arc over. I have never run them but do find them in customers rigs. Have had opportunity to dc hi-pot them. Your 6146 finals see approx 1600 rf volts swing so need to be able to hold off that level. I have DC hi-pot and test a lot of 6146 finals. Good RCA and Sylvania will usually hold off 2000 to 2500 volts. I have tested couple of sets of Chinese and one arced over at 1100 and the other at 1500. So I dont have a lot of experience with them. They just do not have a good reputation. Maybe they are getting better?
>
>
>5. I wont go into a long debate over cathode resistors designed as fuses in detail here as it has been discussed numerous times on this forum. You can search the forum and find all of the previous debate. It is one area where Ken and I agree to disagree. Briefly:
>
>
>A. When 6146 tubes go into thermal runaway due to loss of operating bias and plates are glowing cherry red why dont the cathode resistor blow open? Run your bias voltage down and watch what happens (I dont really recommend this).
>
>
>B. Carbon resistors can stand extreme over current and wattage dissipation for a very long time. Have you ever connected DC supply or Variac to a carbon resistor on your bench and run the current up? You can get them to start smoking and eventually glowing so that you literally see color in them. They wont pop open under those conditions. I would not want enough plate current to flow in my PA to cause the cathode resistors to glow. What would they be protecting then?
>
>
>C. When is last time you blew a cathode resistor open on your HW-101, or SB-102, or Drake T4X or any other 6146 boat anchor transmitter? They all typically measure plate current the same way. Seldom see any post or discussion about cathode resistors popping open on these other forums.
>
>
>D. Only way to experience an instantaneous cathode resistor failure is to have a 6146 anode to cathode arc over. 900 vdc / 5 ohms = 180 amps. (not considering the power supply esr that would add some additional current limiting during the fault). This did not happen back in the KW hybrid heyday with brand new S2001 or 6146B tubes. It is only a more recent phenomenon due to 35 to 40 year old NOS and pulls available that have off gassed and/or have some ingress around tube pin seals after all these years.
>
>
>E. Lastly you never want your cathode to become open circuited. As I previously mentioned in other response. When tube arcs over and momentarily have 160 amps fault current flowing thru 5 ohms then the IR drop is approx 800vdc. The maximum voltage your panel meter can stand is approx 0.40vdc (it is a ua meter movement). A 0,4 vdc meter isnt going to like it when it now tries to measure 800vdc!. If it survives the initial fault now you have an open cathode and it will rise quickly toward Screen grid voltage. The only thing limiting it is the operating bias voltage. It will rise to over 100 vdc (I have measured it). When you place the meter to IP during attempt to reload after you hear that pop the meter will be

stressed again.
>
>
>Kenwood engineers would never fuse the cathode to save "other components" at risk of sacrificing the plate meter. Meter is far more delicate and expensive component.
>
>
>Suggest you figure this out for yourself. Put four 20 ohm carbon resistors in parallel on your service bench and load them up and find out what it takes to get them to "fuse". You are going to see smoke and color before that happens.

OK

With an open on the output or load side of a wattmeter the forward and reflected power should read the same. If you ever see this again make sure you check reflected. If you see 200 watts forward and 200 watts reflected you then know you have an open on the output side of the wattmeter.

Michael,

You said the cathodes resistors are 20 ohms times 4. That's true in the "TS-530 and TS-830 but it is not true in the TS-520 and TS-820. The TS-520 and TS-820 both have only "2" 10 ohm 1 watt cathode resistors.

I recommend you spend some time studying the final amplifier schematics of the TS-520, TS-820, TS-530 and the TS-830. I specifically said the operator was improperly tuning a "TS-520" which has "2" 10 ohm 1 watt cathode resistors not four 20 ohm cathode resistors.

The final tubes are connected in parallel and there is only "1" cathode circuit connected to both tubes. Therefore, both final tubes will see "5 ohms" of cathode resistance.

I'm not confusing the issue but rather you do not seem to understand the differences in the KW hybrid final amplifier cathode circuits nor how the cathode circuits work in the KW hybrids.

If you watch my cathode resistor and metering circuit video you will see exactly what I am talking about. I explain how the TS-520 and TS-820 cathode and metering circuits voltages are calculated, using a TS-520 hybrid with 350ma of cathode current flowing in the final amplifier's cathode circuit. Click on the link below then when the page comes up, fclick on the video link.

http://www.n6wk.com/w5rkl/TS-520%20and%20TS-820%20Cathode%20and%20IP%20metering%20circuit/

46447. Filters For TS-830S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-16 03:15:45 UTC
From: <planningpower@...>
Topic: 46447 Message: 46447

I have a TS-830S with no optional filters. I have not used it yet other than a bench test of receive with a wire inserted in the antenna port. It receives noise just fine so I think it is functional.

I have the following filters from a TS-430S;

YK-88A; 6 kHz AM Filter;

YK-88S; 2.4 kHz SSB Filter;

YK-88SN; 1.8 kHz SSB Filter and

YK-88C; 500 Hz CW Filter.

As far as I understand the manual, the first three are of no use with the '830; the YK-88C can be used with a YG-455C which I do not have.

Is the use of these two filters together mandatory or can just the YK-88C be fitted?

If so, is there any advantage to using the YK-88C alone?

Kerry VK2TIL.

46448. Re: [TS-520_820_530_830] What's wrong with this board?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

From: clifford wright
Topic: 46351 Message: 46448

There seems to be a lot of variation in these resistors. However my own
experience is that in my TS820S they were DEFINITELY stressed. My finals
are always run conservatively and would never be over 250 mA total
current for more than a few seconds.
The main problem is this, if they go out of spec, your meter indication
also is off.
Fortunately they usually fail high. But then you wonder where your
output has gone to.
If they went low the results could be really BAD as you could destroy
your finals while the meter reads a perfectly safe current.
I went through mine very carefully as my meter failed and I had to use a
replacement with a higher sensitivity. So everything was carefully cross
checked to get the calibration accurate on all the meter ranges.
So as I said before I use multi bypassed wire wound resistors set to
exactly 5 Ohms.

Darnit, showing my ignorance again.
I don't have a 520 yet or any books on them.
So I kinda have an excuse for being lost on that one.
Thanks for explaining.
I will watch your video.
Thank you Sir.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael,

You said the cathodes resistors are 20 ohms times 4. That's true in the "TS-530 and TS-830 but it is not true in the TS-520 and TS-820. The TS-520 and TS-820 both have only "2" 10 ohm 1 watt cathode resistors.

I recommend you spend some time studying the final amplifier schematics of the TS-520, TS-820, TS-530 and the TS-830. I specifically said the operator was improperly tuning a "TS-520" which has "2" 10 ohm 1 watt cathode resistors not four 20 ohm cathode resistors.

The final tubes are connected in parallel and there is only "1" cathode circuit connected to both tubes. Therefore, both final tubes will see "5 ohms" of cathode resistance.

I'm not confusing the issue but rather you do not seem to understand the differences in the KW hybrid final amplifier cathode circuits nor how the cathode circuits work in the KW hybrids.

If you watch my cathode resistor and metering circuit video you will see exactly what I am talking about. I explain how the TS-520 and TS-820 cathode and metering circuits voltages are calculated, using a TS-520 hybrid with 350ma of cathode current flowing in the final amplifier's cathode circuit. Click on the link below then when the page comes up, fclick on the video link.

>>
>>
>>
>>1. Use of Artist brushes very good idea. I try not to spray anything as hard to control amount and really direct it and to clean off all the residue.
>>
>>
>>2. OK to try different contact cleaners. Everyone has there favorite. Fader lube is good for carbon trace pots. Usual weak link is the rivet to pc trace interface and not the actual contact fingers unless someone has been in there and pressed on them. They are phosphor bronze with spring temper and can take thousands of spread cycles.Never attempt screwdriver to close them. Only way to change that gap is perhaps attempt a twist. Best to measure contact resistance by applying approx 6 vdc and 1 amp and measuring the millivolt drop across the contacts. Ohm meter test is not good way to find bad contact as no current is used.
>>
>>
>>3. Molex connector is the brand name. The large white connectors on the TS820 are Molex connectors. Just much heavier. A smaller version is used on the TS530 and TS830. You havent lived until you pull 5 or 6 off a board. The pins and sockets in the two connectors are plated and should last long time, but cleaning with contact cleaners and wiping them by multiple cycling can help, but it comes with some risk especially on the TS530 and TS830. I always inspect the connector body pins on foil side of the boards under magnification when board is removed. I insert a plug back on the connector and gently rock back and forth and observe and not uncommon to see a complete 360 degree circumferential crack around the pin and solder "cone".. The pin is floating and can see it moving. In some cases the solder never wetted to the pin. The pin has now developed oxide coating and you cannot simply resolder it. Need to remove the old solder and clean the pin and
resolder.
>>
>>
>>Other problem with repeated cleaning and plug and unplug cycles of these molex connectors is you can rock the connector body and induce a crack in the foil trace right at the pin pad junction. That crack is hard to see due to the solder mask and it can cause you fits.
>>
>>
>>So with 30 to 40 year old radios best not to fix things that are not broken.

46450. Re: [TS-520_820_530_830] What's wrong with this board?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-16 12:59:34 UTC
From: Mike
Topic: 46351 Message: 46450

Michael,

There's nothing wrong with not knowing the differences in cathode resistors in the TS-520/TS-820 final amplifier cathode circuits when compared to the TS-530 and TS-830 final amplifier cathode circuit, especially if you have never own/worked on or studied the 520 and 820 manuals and schematics.The important thing to understand is, there are differences.

The different cathode resistor circuits in all of the KW hybrids, 520, 820, 530, and 830, perform the same thing, the cathode resistors are meter shunts. When current flows in the cathode circuit a voltage is present. This voltage is referred to as "the cathode voltage". This voltage is then applied to the hybrid's meter circuit (meter switch set to IP and the hybrid is in transmit) where the voltage is then displayed on the meter as "current", using the top scale on the meter.

To understand power dissipation in resistors and how power dissipated in a resistor, I recommend you watch my parallel resistor video which is accessed by clicking on the "Basic Ohms Law" link:

www.n6wk.com/w5rkl/Basic Ohms Law/

You can access all my videos starting at the following link:

www.n6wk.com/w5rkl/

The TS-520 and TS-820 operator and service manuals are available for downloading, free, at the following link:

www.n6wk.com/kenwood/

I recommend you download the manuals for the TS-520 and TS-820 along with the various high resolution schematics for all the KW hybrids. Review/study the 520 and 820 final amplifier schematic which will show you there are only two "10 ohm 1 watt" cathode resistors, not four 20 ohm 1/2 watt resistors. As I said, the TS-530 and TS-830 have four 20 ohm 1/2 watt cathode resistors. The bottom line, the different cathode resistor circuits perform the exact same thing, they use the final tube's cathode voltage that is applied to the "IP" meter circuit to measure voltage and display that voltage on the meter's top scale as "current".

It was interesting to me that Mark uses EST to schedule the net
instead of GMT time. Some states change to daylight time and some do
not, so the offset from local time changes. Also a good thing is to
advertise, putting the NET schedules (GMT) and WEB site with the reports
is always a good idea. Mark does a good job, Cudos to him for his work.

Mike W5RKL

I have downloaded MOST of Gordon's (right name?) webpage.
I prefer paper however, wish the darn service manual for TS-830 Gold Label would show up, ordered from Jim at Hybrid almost 3 weeks ago (they are out).
I'd love to sort out the rest of the mods the "Golden Screwdriver" previous owner did to her. Install new tubes and get that baby on air!!
Also bought K4EAA's 3'X4'schenatic. Colored pencils and have clear taped my older manuals where they rip apart at the folds....have begun coloring alot of the circuit traces to faciclitate easier visual usage....

Wasn't aware of all of the different designs (obviously).
Thanks for all your helpful information. I DO learn pretty quick but I'm sure I've been a bit aggravating in my ignorance. Also you men having to cover ground covered numerous times before, at the cost of how many worn out keyboards?

How many newbies have you fellows had to edumacate over the years?
I'll try to get up to speed quickly.
Before all you old farts go SK.
Just kidding.

Man my back is sore today. Too much time in the chair.
Haven't had this much seat time since my NASA test pilot days......

Actually it's the wear and tear of my YL, she's fine looking but sure puts some rough miles on me sometimes..been a busy weekend..Hi Hi

Thanks for all the knowledge Gentlemen, It is much appreciated.

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael,

There's nothing wrong with not knowing the differences in cathode resistors in the TS-520/TS-820 final amplifier cathode circuits when compared to the TS-530 and TS-830 final amplifier cathode circuit, especially if you have never own/worked on or studied the 520 and 820 manuals and schematics.The important thing to understand is, there are differences.

The different cathode resistor circuits in all of the KW hybrids, 520, 820, 530, and 830, perform the same thing, the cathode resistors are meter shunts. When current flows in the

cathode circuit a voltage is present. This voltage is referred to as "the cathode voltage". This voltage is then applied to the hybrid's meter circuit (meter switch set to IP and the hybrid is in transmit) where the voltage is then displayed on the meter as "current", using the top scale on the meter.

To understand power dissipation in resistors and how power dissipated in a resistor, I recommend you watch my parallel resistor video which is accessed by clicking on the "Basic Ohms Law" link:

www.n6wk.com/w5rkl/Basic Ohms Law/

You can access all my videos starting at the following link:

www.n6wk.com/w5rkl/

The TS-520 and TS-820 operator and service manuals are available for downloading, free, at the following link:

www.n6wk.com/kenwood/

I recommend you download the manuals for the TS-520 and TS-820 along with the various high resolution schematics for all the KW hybrids. Review/study the 520 and 820 final amplifier schematic which will show you there are only two "10 ohm 1 watt" cathode resistors, not four 20 ohm 1/2 watt resistors. As I said, the TS-530 and TS-830 have four 20 ohm 1/2 watt cathode resistors. The bottom line, the different cathode resistor circuits perform the exact same thing, they use the final tube's cathode voltage that is applied to the "IP" meter circuit to measure voltage and display that voltage on the meter's top scale as "current".

>>
>>
>>
>>
>>Michael and Terry,
>>
>>If I may add something to Terry's response.
>>
>>Michael, you can easily calculate the approximately power dissipated in each cathode resistor in any of the KW TS-520, TS-820, TS-530, and TS-830 by simply performing simple math calculations using the following formula:
>>
>>P = Isqrd x R
>>
>>Let's assume an operator has improperly tuned their TS-520 resulting in 275ma of IP current.
>>
>>We know that each cathode resistor is approximately 10 ohm 1 watt and the cathode current is 275ma so all we do is use these values and the above formula which will result in approximately .756 watts dissipated in each cathode resistor:
>>
>>.275 x .275 = .075625 x 10 = .756 watts
>>
>>Now lets increase the IP meter indication to 350ma, a much higher improper tuning IP cathode current in the final amplifier. What will the power dissipation in each cathode resistor be? Use the new 350ma IP current value, same 10 ohms 1 watt cathode resistor, and the same formula which results in approximately 1.225 watts dissipated in each cathode resistors:
>>
>>.350 x .350 = .1225 x 10 = 1.225 watts
>>
>>The additional .225 watts over the 1 watt power rating of each cathode resistor will not result in either of the cathode resistors to blow like a fuse.
>>
>>You can also calculate the approximately cathode voltage using any value of IP cathode current by simply using the formula:
>>
>>E = I x R
>>
>>where "E" is the "unknown" cathode voltage, "I" is the value of IP cathode current, and R is the approximate 5 ohms of cathode resistance.

>>
>>For example, if the IP cathode current is "60ma", what will the cathode voltage be and what will the power dissipated in each 10 ohm cathode resistor be? The cathode voltage will be approximately "+.3VDC" or "+300mv":
>>
>>.06 x 5 = .3
>>
>>The approximate power dissipated in each cathode resistor will be .036 watts or 36mw
>>
>>.06 x .06 = .0036 x 10 = .036
>>
>>This same math calculations can be performed on the TS-530 and TS-830 in the same way, using the same formulas.

Or do what I do, post it notes on the front of my rig's speaker!!

Does this stupid Yahoo system work as slow for you guys as it does for me?
About one letter per second.....
Takes forever to do my my "walls of text"
Frustrating. I would think it's my compiuter but it's only a problem on this yahoo. all of my yahoo mail replies, not just here.
Yahoo is junk. Yes, I know I could do "Word" or a notepad, copy and paste.
There is no excuse for the crappy yahoo system but I geuss I'm stuck with it.
All you men have a great day.
Michael///KD0WSJ

That's what alarm clocks are for. Maybe a wrist watch with an alarm would work.

Mark

I had the original fan on my TS520(noS) go bad and replaced it with a nice metal frame muffin fan from the big junk box that just fit the mounting holes. I hooked it to the 120V switch and it does just fine.

On Sunday, December 15, 2013 3:24 PM, Joseph Stiles <stilesjoseph@...> wrote:

Frank,

  If you look at the schematic of the 520 AND the 530/830, you will see that they run off the 100V tap on the transformer. The motors are I believe, wound for 120V...but the lower 100V
has them spinning a bit slower/quieter. I can not remember IF the fan mounting holes have the same dimensions regarding the mounting holes..but as stated earlier...they use the SAME voltage

We have to use EST for the Saturday net as we
follow the Swan net that is in EST. So we butt
right up to the end of their net. They sort of
clear the freq. for us. I like EST better than
GMT for the simple reason the time never changes.
It's always 3:30 Eastern. If it was in GMT, like
the Sunday net, the local time would always be
changing, making it harder for guys to remember, including me.

The Sunday net is GMT because the Icom net that
is in front of us is also on GMT.

So that's the reasoning behind the EST/GMT time.

Michael,
What you need to start doing is typing up your
message in say MS Word, then cut and paste it
into the Yahoo email address and there is no
delay. If you look at the bottom of the group
home page, the email address are near the bottom
under "Group Email Addresses". So if you want to
post a message to the group, it's:

Post
Message:<mailto:ts-520_820_530_830@yahoogroups.com>ts-520_820_530_830@yahoogroups.com

That's the way I do it for the net update that I
post once per week. No way would I sit there and
type out the whole thing each week.

Other than these radio's are fun to operate, a lot of people store these radio's especially if they are collector quality or just have them sitting on shelves for decades. I'm curious as to peoples opinions if it is better on them to keep them operating now and then.

Operate them!

Case in point. A few months ago I bought a couple of TS-530Ss and a TS-830S. One 530 was pretty shabby looking and filthy inside. However, it worked near perfectly and, after I cleaned it up and did a little preventative maintenance on it, it looked and worked like new.

The other 530 was delivered in its original boxes and looked showroom new. The seller explained that the original owner used it for a few weeks, then put it in "dry, temperature controlled, smoke free" storage (for many years). The radio was completely dead and took a LOT of work to get it going again. At the very least many, many connectors had corroded and required disassembly and cleaning. The band switch was especially troublesome.

The TS-830S had also been a victim of disuse. The previous owner testified that for the past 20 years or so he had only used the radio once a year -- on Field Day weekend -- and on only one band, 20 meters. Sure enough, it worked on 20 meters -- and hardly anywhere else. I'm still working on that one. I am happy to report that it's fully functional except for 10 meters now, but it also took a lot of work to make it 100 percent.

Radios are just like any other device. They need to be used in order to be useable.

73,

Craig
W3CRR

My TS-520 gets really crackly and intermittent unless it's run and run hard at least once a week to get it good and hot. After it's been running for a while, all the crackly pots and switches seem to magically clean up and it works just fine. Leave it for more than a couple of weeks, and it's back to sulking and crackling.

Old stuff needs to be run regularly.

I fired up my 1988 Citro?n CX 22TRS for the first time in a few months, and it made some terribly arthritic noises as the hydraulic pressure came up. Not to mention the characteristic "paint-y" smell of stale petrol. After a bit of a run up and down the farm track the creaks had settled down a bit.

Old stuff needs to be run regularly.

Now, all I need to do is get on my bike and go for a cycle for the first time in a few months, to see if I can shake off all my squeaks, rattles and clunks. I'd better just top up the lubrication first, though - sl?inte!

I agree with Joe and his auto example is a perfect analogy.

Temperature and humidity controlled environment means different things to different people. Shelf of a closet does not qualify. Better than being out in the garage but will not prevent the chemical reactions and environmental processes that are taking place within the radio and select components.

A new KW hybrid bought in 1976 and stored all these years even in a temperature and humidity controlled environment will likely not perform flawlessly if energized today.

Tubes are off gassing, rubber will degrade, some components and lubricants have a volatile component that is being evaporated, electrolytic filter cap aluminum oxide dielectric layer loses homogeneous nature and will need to be reformed, carbon resistors are extremely hygroscopic and resistance values will increase and the lead to carbon interface can moisture corrode and develop high resistance contact, all the pots and switches are greased and lubricated and most forms of lubrication have definite shelf life with volatile component evaporating and hardening taking place with only the dryed out soap remaining, carbon pots left at one spot for many years can be a problem, fan bushing felts will be dried out, air variable capacitor phosphor bronze rotor shaft wiper contacts will show green oxide corrosion, mini-din switches have not been exercised, push button switches have not been exercised, band switch contacts can be darkened due to oxidation (we all experience this) .

It goes on and on.

Boat anchor refurb folks know all about carbon composition resistors and paper capacitors.

Putting machinery or electronics in long term storage presents a real challenge. That includes storage of spare parts. The military and the nuclear power industry are industry leaders and spend millions of dollars on this and they dont have all the answers. The nuclear industry has installed spares and has a surveillance program that essentially sees them operating and testing the spare equipment on a regular frequency. They also pull spares from the storeroom and run them. Spare power supplies come to mind. These are pulled and brought up on variac and run on a schedule.

Opponents criticize that such programs test the new spares to death. Might be the case but that is cost of doing business.

I have 4 KW hybrids with one as a daily driver. All have been prepared the same. I do run the others from time to time and not unusual to experience things like a noisy and scratchy AF gain pot until exercised a few times. This is after a relatively short time of non use (several months).

So I say operate the radio and enjoy it unless you are a serious collector and want them as museum pieces and have no expectation of ever seeing them operate again.

Michael,

As I am about 100 emails behind and not sure if this has been answered. A very good way of cleaning some of these tarnished molex connector post is by using an eraser for ink, (gritty end of eraser). These are very easy to shape to fit in between the pins, you will find the method that suits you.

However, I am with Terry, that there is no need to remove molex connectors just for the sake of it. These board types and tracks\foils will easily crack, sometimes unless you using good magnification will not notice and then create another un-necessay problem. I for one when I do find dry joints around these post, completely remove the post, lightly sand\polish the pin and then flow new solder. So far this has not failed me, nor created new issues.

As for cleaning each to their own. I have removed filthy boards and soaked them in mild neutral detergent and then flicked dry. Then somehow the XYL's hairdryer finds its way into my hands and then I dry it off. Finally I have a high volume dog hair dryer, I use that for about 10 minutes to make sure no water is left.

73's

Dave

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

To Terry K9TW ,
Thank you for your kind and considerate advice.
Wise words.
You said that I mentioned I'm cleaning the molex connectors, I don't know what a molex connector is. I could have looked it up and not admitted my ignorance.
"a TS-520 has no molex connectors as it uses wire wrap terminal posts."

What I'm doing is cleaning all the multiple wire plugs that are everywhere.
Coating them, gently wire brushing them then pushing and pulling the plugs on and off 3 times.
Cleaned and coated.
Mechanical connections are one of the biggest problem sources of these antique rigs, in my estimation.

With the wafer switches I'm making custom brushes, some just for particular switches, to gently rub the tarnish off the rotating discs, after spraying, cleaning and coating.
I'm trying Corrosion X after hearing a few Hams swear by that, others swear by Deoxit, I've

bought them all and will try them all and draw my own conclusions, hopefully I'll live long enough to see the differences.
I will be trying the Fader Lube now because you endorse it and seem knowledgable. Ken likes it too, good enough for you guys I'll at least try it.

I'm using small artists paint brushes to apply chems to just the areas I want coated. I don't like the idea of just bathing or spraying down an area with volumes of toxic, expensive chemicals. I know it can and does work to an extent.
Being very careful to avoid the contact fingers, I know how delicate they are, I've repaired a few using Sterling Silver wire, magnifier lamp while wearing 2.25 glasses and fine tip soldering tools. Like doing microsurgery. Quite the challenge. I think it was about 22 gauge silver, I had to restore the springy touch of the contact and solder to it's tip, tough job.

There are some Hams that "dip" or soak boards in chems.....with good results. I've read of using the dishwasher. I'm thinking of gently using the carwash on one I have that is filthy and letting it dry out for days near my woodburner.....
(I recall spraying tuners in the old tv's back in the day.)

(Still not sure what the molex are.)

The man that insisted (by email) the the GE 6146W has PROVEN to him they don't work real well in Kenwood transceivers was very adamant that he'd blown RF boards and Rectifier boards only when he'd used those tubes. He has done the repeated trial and error expensive test, in more than one radio.
For now I'll take his word for it and use other tubes.
Ok, it's not a bias difference (wrong terminology, yes, but HIS words), perhaps internal capacitance differences or I don't know what.
Biasing requirements of the tubes?

I'm surprised that there is such a divide on the opinion of the grid resistors being "pseudo fuses" or not. I understand they establish meter current levels acting as shunts in the cirquit.
(The cobwebs are slowly coming off my electronics memories.)
My impression of K4EAA was that he was one of the "gurus" and his statements were accepted Biblical truths. I geuss not!!!

So, long story short, Thanks Terry for GENTLY stating your position.
Also for tolerating an ignorant egotistical mechanical genius that doesn't know squat about Kenwoods.....
I will do my best in future to more specifically select my wording when writing of a technical nature and will try to not impress so needfully to gratify my ego.
!!!!??
I appreciate you guys putting up with me,
so far!......I'll attempt to not be so annoying in future (good luck with that) and to commit fewer errors to words here!

Answer for me, what is your objection to the Khainese tubes, other than country of origin? I've bought one set, I think that was the pair that one slipped out of my hand and I cracked the glass. I haven't had a set long enough to establish an opinion.

Second, explain Molex connector to me. You said:
"You recently talked about cleaning all the Molex connectors on a TS520 and applying

Corrosion X and presenting it as new idea. Well it is not a new idea."

What I think might be a new idea (I'm sure somebody has done it before) is using tiny brushes to remove even more tarnish off the rotating discs of the wafer switches that Deoxit spray didn't. While avoiding touching or damaging the fingers of the springy contacts. I really like the idea.
I seem to be having good success with rigs that are giving trouble from bad connections in this switching area.
Some discs are black with corrosion even after spraying, when I'm done most look like new.
The HV cage presents special challenges since it's so crowded. I'm making brushes for each area that are different as I find a way to get at them, away from the delicate contacts.

Also, what is your personal opinion of the apparent difference of opinion on whether the Cathode? resistors act as "pseudo fuses" as Ken calls them?

I'm running about 40 hours now on 2 hours sleep last night. Been doing that alot lately, pushing and testing myself mentally and physically, on purpose.
While it helps me to understand my limits and capabilities, it also turns me into a short tempered, dimwit a**hole, that's offended easily.

I'm expecting great turmoil in our country soon. I need to know my limits and also know I can "operate" under duress and for long hours.
I hope I'm wrong regarding the turmoil.

I pray I'm wrong.

In summation, answer about the Khainese tubes?
What are Molex connectors?
Your opinion on the "fuses" debate please.

Thank you for your time and patience Terry.

"Communications will be key"
Michael///KD0WSJ

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael

I dont know you. I dont know your formal education level. I dont know your fundamental electronic knowledge. I dont know your fundamental radio theory knowledge, I do not know your KW hybrid knowledge or experience.

There is nothing wrong with being new. We all were at one time. However, a new person who listens and asks is far more likely to be taken seriously than one who speaks when clearly has little or no knowledge of the subject.

All I or anyone else on this forum can go by is what you say and how you say it in writing. After about 3 or 4 posts and responses a picture is painted. The perception may be wrong, but important for you to know what that perception is and to care about it and to take action to change it if it is wrong. Perception is always the other guys reality.

Regarding perception it is clear you have lots of zeal and are anxious to help, but it is also very obvious that you lack basic electronic knowledge, vacuum tube fundamentals, and KW hybrid knowledge and experience OR you have become very very rusty. Time will tell.

One of the very worst things any of us can do on this forum is bum dope people. Any and all of us should be corrected when we give out bad or just plain wrong technical advice. We are adults and should not take that as personal attack. Sometimes we just make a mistake or typo and other times we are out in left field. That includes me.

There will always be professional differences of opinion but those should be debated on the merits of the technical basis that each side presents and not on subjective or anecdotal or tribal myths and beliefs. Far too much of that abounds on the various ham radio forums today. For example, you will always have those who insist that matched pair finals are better or necessary and when quizzed about only one bias voltage pot and no ability to individually set the zero signal plate current they huff and puff and tap dance around.

You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea. Many people recommend cleaning molex connectors as first step in resolving any and all operational issues with a hybrid. I am in the camp that this is silly and bad advice. It represents risk of immediate damage and introducing latent failure and simply is not required. Yes from time to time it will resolve an issue, but what really fixed the problem? Experiential based troubleshooting is fine, but once that is exhausted have to break out the schematic and test gear. Also, Corrosion X is commonly used by the RC model boat folks who routinely immerse their electronics. I never submerge any of my KW hybrids. Deoxit and Fader lube properly applied works great and no oily smelly greasy residue. By the way a TS-520 has no molex connectors as it uses wire wrap terminal posts.

So I appreciate your zeal and interest and eagerness to help, but it appears to me at this stage of your development you would be better served reading the post, asking questions, and learning. However, it is your call if you wish to continue responding as you have been. You need to earn respect and that will come with the quality of your questions and responses.

I am not telling you that you are not welcome on this forum. I am not the owner and not in position to say one way or another. What I can offer is if you want to learn there are people here with 40 to 50 years ham radio knowledge and experience who grew up in the tube era and who have 10 to 15 years of hands on KW hybrid repair and they freely share any and all of their knowledge and experience. Up to you if you want to avail yourself of that valuable resource. Of course as we age we are looking for new folks to take our place holding up the tent poles. Those people dont get produced over night.

Just dont be too thin skinned or have fragile self esteem. When someone corrects you it is meant to help you and every new person who is following along. This is a technical forum and a KW hybrid is a complex engineering marvel. To be taken seriously you need to be credible.

"Reburbing" KW hybrids by cleaning, lubing, and painting them does not make anyone a KW hybrid service tech. Yes cosmetic cleaning is a part of repair, but it takes knowledge, experience, proper test gear, and knowing how to use it to run the Service Manual steps to restore a KW hybrid to factory performance level. Sure you can run the Owner Instruction Manual Maintenance section steps and get rig in pretty good shape. It just depends on how many golden screw drivers have been inside the rig and what your definition of performance

and quality is.

Any technical discipline comes with its own parlance and jargon and using the terminology in the proper context speaks volumes about the persons knowledge and experience level.

So sorry if I hurt your feelings, but very hard to sit on sidelines and read advice that the goes way beyond not using the parlance properly. So to be 100% honest with you in my mind the jury is still out. Hopefully, you care enough to accept the challenge and prove me and others wrong.

Terry K9TW

The mind boggles. Several radios, On shelves, Doing nothing but corroding and deteriorating. Wow. Isn't there a better use for them? Door-stops perhaps?

Or maybe donate one (just a loan, at least to begin with) to a Boy Scout Troop or Explorer Post, or a 4-H group, To the Girl Scouts if there is a group of 'em with that sort of bent?

The local civic center teen hang-out place with a staff, or a school in your area? Offer to Elmer interested people using the donated/loaned gear? Teach a BSA Merit Badge class? Stir up a little new blood for this hobby?

Even take one to the local RETIREMENT HOME or "ELDER-CARE" facility, if you can't stand kids.

OR you could just leave 'em in the closet for someone to eventually throw in the dumpster or sell for a pittance on eBay, to be chopped uo for spares.

Is it a case of, "He who dies with the biggest pile of radios, unused, new or nearly, still in the box, wins a Kewpie Doll at the Pearly Gates," and, me being an agnostic, nobody ever told me?

I keep hearing about hams with MANY 'spare' rigs - not just two or three, but half a dozen and more - all just sitting there on shelves or in basements, doing nothing with them because they've 'moved on' to other things. It's a free country, do what you want with your stuff, of course. But isn't there a better use for it? (Donating it gets you a tax write-off, maybe, depending on to where. You don't have to store the stuff any more, either. This could make room to stash your twelfth set of golf clubs, maybe?)

I personally, being from the other side of the tracks, and someone who has had to scrape and scrimp and repair and scrimp some more just to get ONE barely-working rig, find this very confusing, to say the least. A surplus of equipment has never been a problem I've needed to deal with, truth be told. (Never had the handicap of being good-looking, either. I'm told that is quite the burden to bear.)

Enlighten me. Why would you just stockpile gear, and not find some way to get it USED, by someone, and perhaps get some new folks into the hobby?

Particularly the "other than usual" demographics kind of people.

I have been asking around, talking to High Schoolers and Junior High Schoolers ("Middle School" they call it now...) The answers I got were quite surprising. Most of the kids don't know the hobby even EXISTS, unless they have a relative, or the parent of a friend who is a Ham.

And it categorically is NOT the technical nature of the hobby which keeps them away, I am finding, Particularly the young, and even more specifically, young females, the ones who know what Ham radio actually IS, shy away from amateur radio for one main reason,

(Before I go on, know that I fit in here myself in all but ONE category they name, so don't get your knickers in a twist! I'm just putting out what the kids are telling me when I ask and they can't evade answering truthfully!)

Those who know about it at all perceive the hobby as being only, strictly, JUST, FOR:

OLD
FAT
GEEKY
GUY.

(I fit in three out of four of those myself, and at one point it was all four. But I've lost a lot of weight since I became crippled with arthritis. And please do NOT be offended. This was the result of a survey I did, and the question for those who knew what Ham radio was read, "Describe the typical Amateur Radio hobbyist." I made a sort of equivalency table, a lot of terms got lumped together, mainly things like "dork" and "dweeb" were all lumped into "geeky," for instance. Some of the terms were rather offensive, and I pruned those heavily. Leave it to "geeky" as a close enough descriptor.)

Why, please, can not some of us, despite our perceived 'handicap' take at least a few of these excess pieces of gear out of the basement, and spread a little radio frequency geekiness around?

Perhaps even move that demographic a tad, in some of those areas? We're sort of stuck with "GEEKY" I'm afraid, but the rest, well, can't we make an effort?

Wouldn't any of -you- enjoy a QSO with a young female once in awhile? I've almost got my cheerleading, blonde, sixteen-year-old grand-daughter convinced to give it a whirl......

She's a great kid, and I wouldn't mind a bit letting her chat with y'all. (For one thing, I -know- you'll be polite and perfect gentlemen, seeing as you're HAMS, and not CB-types. Best chaperone a grampa can get, don't you think? Besides the double-barreled 12-gauge, that is.)

I rather enjoy talking to kids, myself, of either gender. They have such different viewpoints. For instance, I volunteer at my wife's school, as often as there is a job needing done. (I fix a lot of computers and network issues, there's an iMac in need of a motherboard swap and I've got to dig one out of my junkbox, before the end of the week and get to that...)

There are definitely some fifth- and sixth- grade kids who could be easily Elmered to at least a Tech license, and mentored to General or higher before they got out of high school. And this is a tiny, rural school in farm and orchard country. What might be done at a big school?

If I can get a radio or two ahead - having only my one 520SE puts this out of reach at the moment - I have made arrangements with the high school in the town where my wife teaches elementary school. to try to start a club after school hours. The Superintendent has already signed off on it, at least to give it a try, and the Physics teacher will be helping me get it going. (He is studying for his Tech now. I'm helping out with his VHF gear, he likes the upper frequencies more than HF, he thinks, already. I hope to change that before it's over.)

Me only having one 2-meter FM mobile, and the 520SE, isn't enough to get the ball rolling; but for the moment it's all I have. (Hand-held, a VX7R, was stolen, my ex-wife sold my FT101Z for five bucks, right before she filed for divorce. I'm starting from behind the curve a bit, gear-wise.)

We're going to be trying to raise some money to buy used stuff for the kids to get started on. And I'm donating my extra VTVM, a signal generator, a soldering station, a power supply or two, and a DMM for the start of their work bench, too. All elderly junk I've refurbished over the summer, but it's a start.

If I can do it, and this WILL get done, starting with pretty much nothing and most assuredly with no money to speak of, why cannot some of the fraternity of amateurs, of which in my opinion this list is one of the better subsets, at least try to do the same in their own areas?

I know that not everyone has the time, nor the inclination, to mess with a bunch of snot-nosed, young, get-off-my-lawn whippersnappers. Kids take a lot of extra effort. But I can't be the ONLY one who thinks it would be a good idea to get the next generation involved in this stuff.

Or can I be?

Last I'll say about it, on the list. It's just something that has bothered me for quite awhile now, and I intend to do something about it. As it is NOT directly associated with hybrid Kenwoods, or even more than indirectly with old rigs of any sort, I won't continue this here. But anyone who wishes to discuss this with me is welcome to email me directly at the address this came from.

Thanks for the iseas.
I like the eraser method, the ink type are gritty and would work wonders on a heavily tarnished disc.

I concur on the Molex issue. I will certainly be more judicious in tampering with them.

(For cleaning heavily tarnished wafer discs)
What I keep thinking about for brushes is to take Bronze/brass type "toothbrush"" that you'll often see at gun shows.
Bristles are about 1/2' long.
Take one bundle of those bristles, wrap fine wire around them just to bundle them up.
These have been removed from a brush, OK?
Are you with me?

I have some 14 gauge brass sheet. I'll cut a strip about 3' or so long, maybe1/4" wide.
Drill a 1/8" hole in the end centered back 3/16" from the end.
Carefully grind or file to a rounded end. Remove all burrs, insert bundle of bristles so they are protruding through 1/16".
Whip out my high wattage solder iron, 4% silver solder, solder the 1/16" side.
Trim bristles to just under 1/4" on the other side.
Just short enough the brush will fit in between the closest wafer boards easily.
when brushing, each wafer has an area that is void of contact fingers.
This is the area to apply the brush while SLOWLY rotating the bandswitch, taking care not to pinch any bristles or snip off any brass wire from your brush.
Make double sure, no, triple sure you don't drop and leave any brush wires into the circuit for more fun later!!
I was using tapered handle stainless brushes. Big toothbrush on one end and narrow 1/4" wide on the other end.
I was trimming the small, narrower end of brush bristles to under 1/4", still a tight fit in alot of areas.
I found some on eBay that are just like what I was making!!
"Doc's Fly Box" has them. I just checked, his eBay ID is "sierraflyfish" and the item number is (390656564639), they are like $3.50 each.
Just got more in yesterday. Real handy they are.
I'm making different shapes of brushes for each wafer as each presents a different set of issues as far as avoiding damage to contact fingers.
I've been using some of my "pin vises" and trying different bronze gun bore cleaning brushes, bastardizing those, need to find something smaller than .22, maybe order some .17 brushes, do they make them that small?
The last RF board I worked on is out of a TS-820S. I found it very helpful to remove the board and place into a 3 axis "Panavise". I'm using a magnifying lamp, like you see on K4EAA's bench,
(his is gold though, I want a gold one....) with 2.00 reading glasses, 10X eyes?
I think I could spend voluminous time making a set just for the HV cage.
Dadgum crouded in there.
Thanks for the eraser idea. I like it.

I appreciate your help and everyones patience and guidance.
Now if you'd just fix this dang 820S dig readout for me.
I'll be doing my first "solder through hole" repair this morning on the X54-1160-00 board. Tried swapping the whole 2 board box out and it got me nowhere. I'm suspecting the dig display itself, or power input to boards.
Pulled the front off another 820S and yanked the dig display, plugged that one in, and still nadda. (My annonomous new freind said that the Casio CM 607 calculator display uses same tube, bought one cheap and have a bid on another, you know, the guy that doesn't like GE W tubes?).

My troubleshooting skills have always sucked.
Wonder if Jim at Hybrid or Ken could use somebody to sweep the floors??
My fine tip Weller iron is hot, about to start. Wish me luck.

Need a break.
You all have a great Day!!
Oh yeah, the "King of shipping", Johnathan at Hybrid said my dang 830S service manual finally came in. I want that one running!!! (Gold Label)

Subject: RE: [TS-520_820_530_830] What's wrong with this board?

Michael,

As I am about 100 emails behind and not sure if this has been answered. A very good way of cleaning some of these tarnished molex connector post is by using an eraser for ink, (gritty end of eraser). These are very easy to shape to fit in between the pins, you will find the method that suits you.
However, I am with Terry, that there is no need to remove molex connectors just for the sake of it. These board types and tracks\foils will easily crack, sometimes unless you using good magnification will not notice and then create another un-necessay problem. I for one when I do find dry joints around these post, completely remove the post, lightly sand\polish the pin and then flow new solder. So far this has not failed me, nor created new issues.

As for cleaning each to their own. I have removed filthy boards and soaked them in mild neutral detergent and then flicked dry. Then somehow the XYL's hairdryer finds its way into my hands and then I dry it off. Finally I have a high volume dog hair dryer, I use that for about 10 minutes to make sure no water is left.

73's
Dave

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

To Terry K9TW ,
Thank you for your kind and considerate advice.
Wise words.
You said that I mentioned I'm cleaning the molex connectors, I don't know what a molex connector is. I could have looked it up and not admitted my ignorance.
"a TS-520 has no molex connectors as it uses wire wrap terminal posts."

What I'm doing is cleaning all the multiple wire plugs that are everywhere.
Coating them, gently wire brushing them then pushing and pulling the plugs on and off 3 times.
Cleaned and coated.
Mechanical connections are one of the biggest problem sources of these antique rigs, in my estimation.

With the wafer switches I'm making custom brushes, some just for particular switches, to gently rub the tarnish off the rotating discs, after spraying, cleaning and coating.
I'm trying Corrosion X after hearing a few Hams swear by that, others swear by Deoxit, I've bought them all and will try them all and draw my own conclusions, hopefully I'll live long enough to see the differences.
I will be trying the Fader Lube now because you endorse it and seem knowledgable. Ken likes it too, good enough for you guys I'll at least try it.

I'm using small artists paint brushes to apply chems to just the areas I want coated. I don't like the idea of just bathing or spraying down an area with volumes of toxic, expensive chemicals. I know it can and does work to an extent.
Being very careful to avoid the contact fingers, I know how delicate they are, I've repaired a few using Sterling Silver wire, magnifier lamp while wearing 2.25 glasses and fine tip soldering tools. Like doing microsurgery. Quite the challenge. I think it was about 22 gauge silver, I had to restore the springy touch of the contact and solder to it's tip, tough job.

There are some Hams that "dip" or soak boards in chems.....with good results. I've read of using the dishwasher. I'm thinking of gently using the carwash on one I have that is filthy and letting it dry out for days near my woodburner.....
(I recall spraying tuners in the old tv's back in the day.)

(Still not sure what the molex are.)

The man that insisted (by email) the the GE 6146W has PROVEN to him they don't work real well in Kenwood transceivers was very adamant that he'd blown RF boards and Rectifier boards only when he'd used those tubes. He has done the repeated trial and error expensive test, in more than one radio.
For now I'll take his word for it and use other tubes.
Ok, it's not a bias difference (wrong terminology, yes, but HIS words), perhaps internal capacitance differences or I don't know what.
Biasing requirements of the tubes?

I'm surprised that there is such a divide on the opinion of the grid resistors being "pseudo fuses" or not. I understand they establish meter current levels acting as shunts in

the cirquit.
(The cobwebs are slowly coming off my electronics memories.)
My impression of K4EAA was that he was one of the "gurus" and his statements were accepted Biblical truths. I geuss not!!!

So, long story short, Thanks Terry for GENTLY stating your position.
Also for tolerating an ignorant egotistical mechanical genius that doesn't know squat about Kenwoods.....
I will do my best in future to more specifically select my wording when writing of a technical nature and will try to not impress so needfully to gratify my ego.
!!!!??
I appreciate you guys putting up with me,
so far!.....I'll attempt to not be so annoying in future (good luck with that) and to commit fewer errors to words here!

Answer for me, what is your objection to the Khainese tubes, other than country of origin? I've bought one set, I think that was the pair that one slipped out of my hand and I cracked the glass. I haven't had a set long enough to establish an opinion.

Second, explain Molex connector to me. You said:
"You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea."

What I think might be a new idea (I'm sure somebody has done it before) is using tiny brushes to remove even more tarnish off the rotating discs of the wafer switches that Deoxit spray didn't. While avoiding touching or damaging the fingers of the springy contacts. I really like the idea.
I seem to be having good success with rigs that are giving trouble from bad connections in this switching area.
Some discs are black with corrosion even after spraying, when I'm done most look like new.
The HV cage presents special challenges since it's so crowded. I'm making brushes for each area that are different as I find a way to get at them, away from the delicate contacts.

Also, what is your personal opinion of the apparent difference of opinion on whether the Cathode? resistors act as "pseudo fuses" as Ken calls them?

I'm running about 40 hours now on 2 hours sleep last night. Been doing that alot lately, pushing and testing myself mentally and physically, on purpose.
While it helps me to understand my limits and capabilities, it also turns me into a short tempered, dimwit a**hole, that's offended easily.

I'm expecting great turmoil in our country soon. I need to know my limits and also know I can "operate" under duress and for long hours.
I hope I'm wrong regarding the turmoil.

I pray I'm wrong.

In summation, answer about the Khainese tubes?
What are Molex connectors?
Your opinion on the "fuses" debate please.

Thank you for your time and patience Terry.

"Communications will be key"
Michael///KD0WSJ

Subject: Re: [TS-520_820_530_830] What's wrong with this board?

Michael

I dont know you. I dont know your formal education level. I dont know your fundamental electronic knowledge. I dont know your fundamental radio theory knowledge, I do not know your KW hybrid knowledge or experience.

There is nothing wrong with being new. We all were at one time. However, a new person who listens and asks is far more likely to be taken seriously than one who speaks when clearly has little or no knowledge of the subject.

All I or anyone else on this forum can go by is what you say and how you say it in writing. After about 3 or 4 posts and responses a picture is painted. The perception may be wrong, but important for you to know what that perception is and to care about it and to take action to change it if it is wrong. Perception is always the other guys reality.

Regarding perception it is clear you have lots of zeal and are anxious to help, but it is also very obvious that you lack basic electronic knowledge, vacuum tube fundamentals, and KW hybrid knowledge and experience OR you have become very very rusty. Time will tell.

One of the very worst things any of us can do on this forum is bum dope people. Any and all of us should be corrected when we give out bad or just plain wrong technical advice. We are adults and should not take that as personal attack. Sometimes we just make a mistake or typo and other times we are out in left field. That includes me.

There will always be professional differences of opinion but those should be debated on the merits of the technical basis that each side presents and not on subjective or anecdotal or tribal myths and beliefs. Far too much of that abounds on the various ham radio forums today. For example, you will always have those who insist that matched pair finals are better or necessary and when quizzed about only one bias voltage pot and no ability to individually set the zero signal plate current they huff and puff and tap dance around.

You recently talked about cleaning all the Molex connectors on a TS520 and applying Corrosion X and presenting it as new idea. Well it is not a new idea. Many people recommend cleaning molex connectors as first step in resolving any and all operational issues with a hybrid. I am in the camp that this is silly and bad advice. It represents risk of immediate damage and introducing latent failure and simply is not required. Yes from time to time it will resolve an issue, but what really fixed the problem? Experiential based troubleshooting is fine, but once that is exhausted have to break out the schematic and test gear. Also, Corrosion X is commonly used by the RC model boat folks who routinely immerse their electronics. I never submerge any of my KW hybrids. Deoxit and Fader lube properly applied works great and no oily smelly greasy residue. By the way a TS-520 has no molex connectors as it uses wire wrap terminal posts.

So I appreciate your zeal and interest and eagerness to help, but it appears to me at this stage of your development you would be better served reading the post, asking questions,

and learning. However, it is your call if you wish to continue responding as you have been. You need to earn respect and that will come with the quality of your questions and responses.

I am not telling you that you are not welcome on this forum. I am not the owner and not in position to say one way or another. What I can offer is if you want to learn there are people here with 40 to 50 years ham radio knowledge and experience who grew up in the tube era and who have 10 to 15 years of hands on KW hybrid repair and they freely share any and all of their knowledge and experience. Up to you if you want to avail yourself of that valuable resource. Of course as we age we are looking for new folks to take our place holding up the tent poles. Those people dont get produced over night.

Just dont be too thin skinned or have fragile self esteem. When someone corrects you it is meant to help you and every new person who is following along. This is a technical forum and a KW hybrid is a complex engineering marvel. To be taken seriously you need to be credible.

"Reburbing" KW hybrids by cleaning, lubing, and painting them does not make anyone a KW hybrid service tech. Yes cosmetic cleaning is a part of repair, but it takes knowledge, experience, proper test gear, and knowing how to use it to run the Service Manual steps to restore a KW hybrid to factory performance level. Sure you can run the Owner Instruction Manual Maintenance section steps and get rig in pretty good shape. It just depends on how many golden screw drivers have been inside the rig and what your definition of performance and quality is.

Any technical discipline comes with its own parlance and jargon and using the terminology in the proper context speaks volumes about the persons knowledge and experience level.

So sorry if I hurt your feelings, but very hard to sit on sidelines and read advice that the goes way beyond not using the parlance properly. So to be 100% honest with you in my mind the jury is still out. Hopefully, you care enough to accept the challenge and prove me and others wrong.

Terry K9TW

Gonna go work some CW at 3.555 Mhz. My speed sux.

Or the other possibility that comes to my mind is get them to the patriot/militia movement. If I could get radios cheaper or free from damp dusty basements I could detail and service them and get them out cheap to those that will be there when it all goes south.

You letter brought a tear to my eye Wes.
You're a good man. I'm very impressed.
I hope to be be working with a teenager soon to try to teach him, I'm hearing he's real interested but we have to figure out how to get him around.
His grandfather is a nut but wants me to teach the kid. Keeps telling me about him but that's as far as it's gone....
Good luck with your project. It's a worthwhile endeavor.
You'll be blessed for your efforts I'm sure.

"All it takes for evil to suceed is for good men to do nothing".

You mature fellows not sharing your knowledge and your wealth of ratholed radios and assets that are going to waste (or about to be stolen by the banksters and politicians) is one of the things wrong
with this decaying country today.
Get off your butts.

I'm proud of you Wes.

The mind boggles. Several radios, On shelves, Doing nothing but
corroding and deteriorating. Wow. Isn't there a better use for them?
Door-stops perhaps?

Or maybe donate one (just a loan, at least to begin with) to a Boy Scout Troop or Explorer Post, or a 4-H group, To the Girl Scouts if there is a group of 'em with that sort of bent?

The local civic center teen hang-out place with a staff, or a school in your area? Offer to Elmer interested people using the donated/loaned gear? Teach a BSA Merit Badge class? Stir up a little new blood for this hobby?

Even take one to the local RETIREMENT HOME or "ELDER-CARE" facility, if you can't stand kids.

OR you could just leave 'em in the closet for someone to eventually throw in the dumpster or sell for a pittance on eBay, to be chopped uo for spares.

Is it a case of, "He who dies with the biggest pile of radios, unused, new or nearly, still in the box, wins a Kewpie Doll at the Pearly Gates," and, me being an agnostic, nobody ever told me?

I keep hearing about hams with MANY 'spare' rigs - not just two or three, but half a dozen and more - all just sitting there on shelves or in basements, doing nothing with them because they've 'moved on' to other things. It's a free country, do what you want with your stuff, of course. But isn't there a better use for it? (Donating it gets you a tax write-off, maybe, depending on to where. You don't have to store the stuff any more, either. This could make room to stash your twelfth set of golf clubs, maybe?)

I personally, being from the other side of the tracks, and someone who has had to scrape and scrimp and repair and scrimp some more just to get ONE barely-working rig, find this very confusing, to say the least. A surplus of equipment has never been a problem I've needed to deal with, truth be told. (Never had the handicap of being good-looking, either. I'm told that is quite the burden to bear.)

Enlighten me. Why would you just stockpile gear, and not find some way to get it USED, by someone, and perhaps get some new folks into the hobby?

Particularly the "other than usual" demographics kind of people.

I have been asking around, talking to High Schoolers and Junior High Schoolers ("Middle School" they call it now...) The answers I got were quite surprising. Most of the kids don't know the hobby even EXISTS, unless they have a relative, or the parent of a friend who is a Ham.

And it categorically is NOT the technical nature of the hobby which keeps them away, I am finding, Particularly the young, and even more specifically, young females, the ones who know what Ham radio actually IS, shy away from amateur radio for one main reason,

(Before I go on, know that I fit in here myself in all but ONE category they name, so don't get your knickers in a twist! I'm just putting out what the kids are telling me when I ask and they can't evade answering

truthfully!)

Those who know about it at all perceive the hobby as being only, strictly, JUST, FOR:

OLD
FAT
GEEKY
GUY.

(I fit in three out of four of those myself, and at one point it was all four. But I've lost a lot of weight since I became crippled with arthritis. And please do NOT be offended. This was the result of a survey I did, and the question for those who knew what Ham radio was read, "Describe the typical Amateur Radio hobbyist." I made a sort of equivalency table, a lot of terms got lumped together, mainly things like "dork" and "dweeb" were all lumped into "geeky," for instance. Some of the terms were rather offensive, and I pruned those heavily. Leave it to "geeky" as a close enough descriptor.)

Why, please, can not some of us, despite our perceived 'handicap' take at least a few of these excess pieces of gear out of the basement, and spread a little radio frequency geekiness around?

Perhaps even move that demographic a tad, in some of those areas? We're sort of stuck with "GEEKY" I'm afraid, but the rest, well, can't we make an effort?

Wouldn't any of -you- enjoy a QSO with a young female once in awhile? I've almost got my cheerleading, blonde, sixteen-year-old grand-daughter convinced to give it a whirl......

She's a great kid, and I wouldn't mind a bit letting her chat with y'all. (For one thing, I -know- you'll be polite and perfect gentlemen, seeing as you're HAMS, and not CB-types. Best chaperone a grampa can get, don't you think? Besides the double-barreled 12-gauge, that is.)

I rather enjoy talking to kids, myself, of either gender. They have such different viewpoints. For instance, I volunteer at my wife's school, as often as there is a job needing done. (I fix a lot of computers and network issues, there's an iMac in need of a motherboard swap and I've got to dig one out of my junkbox, before the end of the week and get to that...)

There are definitely some fifth- and sixth- grade kids who could be easily Elmered to at least a Tech license, and mentored to General or higher before they got out of high school. And this is a tiny, rural school in farm and orchard country. What might be done at a big school?

If I can get a radio or two ahead - having only my one 520SE puts this out of reach at the moment - I have made arrangements with the high school in the town where my wife teaches elementary school. to try to start a club after school hours. The Superintendent has already signed

off on it, at least to give it a try, and the Physics teacher will be helping me get it going. (He is studying for his Tech now. I'm helping out with his VHF gear, he likes the upper frequencies more than HF, he thinks, already. I hope to change that before it's over.)

Me only having one 2-meter FM mobile, and the 520SE, isn't enough to get the ball rolling; but for the moment it's all I have. (Hand-held, a VX7R, was stolen, my ex-wife sold my FT101Z for five bucks, right before she filed for divorce. I'm starting from behind the curve a bit, gear-wise.)

We're going to be trying to raise some money to buy used stuff for the kids to get started on. And I'm donating my extra VTVM, a signal generator, a soldering station, a power supply or two, and a DMM for the start of their work bench, too. All elderly junk I've refurbished over the summer, but it's a start.

If I can do it, and this WILL get done, starting with pretty much nothing and most assuredly with no money to speak of, why cannot some of the fraternity of amateurs, of which in my opinion this list is one of the better subsets, at least try to do the same in their own areas?

I know that not everyone has the time, nor the inclination, to mess with a bunch of snot-nosed, young, get-off-my-lawn whippersnappers. Kids take a lot of extra effort. But I can't be the ONLY one who thinks it would be a good idea to get the next generation involved in this stuff.

Or can I be?

Last I'll say about it, on the list. It's just something that has bothered me for quite awhile now, and I intend to do something about it. As it is NOT directly associated with hybrid Kenwoods, or even more than indirectly with old rigs of any sort, I won't continue this here. But anyone who wishes to discuss this with me is welcome to email me directly at the address this came from.

Michael

Just so you know there it nothing different or special about a Gold Emblem TS-830 other than the gold lettered emblem on bottom of the VFO face plate instead of a Silver emblem.

Some believe it meant that rig came full filtered from the factory and some say had different Murata 455khz ceramic filter (K12 instead of K5), but the Murata 2nd IF filter change came in about the 3 million series and had nothing to do with being a gold emblem rig. The gold emblem did not introduce any circuitry changes or performance enhancements.

You will even find original 1 million series TS-830s that people have installed gold emblem VFOs in them. Almost impossible to tell an original Gold Emblem TS-830 unless you know someone who bought factory new one and has the original invoice to share with you and can tell you the year they bought it and the serial number.

Of course good to mention it when you go to sell the rig as the uninformed buyer might pay extra on ebay to get a gold emblem TS-830 thinking it represents some thing special.

Might I suggest that the kids of today will be much more inclined to stay after school and work on Arduino projects or perhaps a RTL2832U dongle.

SDR will much more interesting to the average kid. They like computers and software and would take to this easily.

Cost would also be much much lower than KW hybrids and more hands on participation at same time.

I cant even spell "I/Q" so I could not lead such a youth group.

My guess is already being done in some middle and/or high schools.

I love KW hybrids but just dont see the youth of today being lead to them in any number that would make a difference.

All good responses to this post. I'll put in my 2 cents in, as I have a TS-520 and been collecting some of the accessories that went with it, the matching speaker and VFO, and then some of the other parts as I can afford them.
I try to fire the '520 up at least once a month when possible for "grins & giggles" and have it and my regular workhorse rig (Icom IC-718) connected to an antenna switch. Then all I have to do is decide which radio I want to use that moment, flip the antenna switch to that radio, and get talking. My next project is a Yaesu FT-101E that a fellow ham gave to me due to he needed the room and didn't want it anymore. Once I go through it and have it back to running condition, I'll hook it up through my antenna switch, and then chose either it, the '520, or the '718 to get on the air.
I have a few old receivers that are sitting on a shelf that I need to do the same with, so they don't go bad.

Just be careful that your antenna switching arrangement is fool proof and will not allow accidental transmit RF to front end of either rig. Some fellows use patch cords and swap them around and more than one KW hybrid Ant Step Up Transformer and RF Amp mosfet has bit the dust.

Terry, as usual, displays great wisdom.

I became a big fan of "fail safe" patch cords during my broadcasting days. When used for radio selection, antenna switches -- especially the common, run-of-the-mill ones -- scare me.

73 and Happy Holidays to all!

Clearly labelling your cables with something that won't come off - like those PVC letter sleeves that slip over cable ties, they're good - is always a decent plan too.

Turns out TS520s don't load up too well into a 440-470MHz folded dipole. No harm done, fortunately.

Craig

I know you are fully aware, but if going to make a patch panel or patch cables good idea to use different connectors on opposite ends of the jumper. For example could use BNC on one end and UHF on the other. Then connect the transceivers to the BNC ends and antennas to the UHF ends. Pretty fool proof system.

Also some cheap antenna switches may not have good port to port isolation.

Some mfg. list it in terms of db. For example 60 db would mean if you were transmitting on one transceiver at 100 watts out the other transceiver connected to this switch in RX mode would see RF voltage at 1000/1. 100 watts would be approx 71 rf volts and the other port would see approx 71mv of rf. That would not hurt a KW hybrid front end.

I just know I have made a little money repairing KW hybrids that experienced accidental transmit rf.

Of course it can be done safely. Just has to be done smartly.

In one case a fellow went to hamfest with some buddies. One of them brought home a boat anchor treasure to this fellows shack and put it at the operating position to test it. After they left this fellow went to use his KW hybrid and found he no longer had receive. Seems his buddies took care of his Ant Step Up transformer for him!

Fellows:

I certainly appreciate the endorsements, but before you pack up your rig with intentions of sending it my way best to contact me off list first.

I am doing a little more work now as we are not going to Florida this year as I remain under care of hemotologist from my lung clot episode back in June. So good to have something to do other than staring out the window at the snow.

While I am doing more work I am getting a little bit picky about what I take on so please contact off list to discuss. Sometimes I may be able to help talk you through a repair. Also I no longer just do what I call cafeteria or menu style repairs. Only doing repairs followed by complete service manual alignment. I do not perform refurbishments or restoration. For that I think KE7OAY Jim Showker or W0NTA Dick Housden may be ones you should contact. WB0IQK Mark Gilger also maintains a list of techs.

Once again I really appreciate your business and the recommendations.

Happy Holidays and Best 73s

Even safer - never allow any lesser rig to share aerials with your Trio hybrid. Don't even have them in the same shack.

What do you mean, you've only got one shack in the house?

I'll third it.
While I've got you men here,
What is the logical train of looking into a failed 820S dig display?
I wish the manuals had a block troubleshooting diagram.
I'll figger it out but I like to cheat.
Save me a day of work and study please?
Didn't get to the solder-through-boards repair this morning. Got tied up on microeffect.com talking comms and nwo stuff. Also my shortcuts for studying the ham tests, DON'T READ THE WRONG ANSWERS!!
For eham.net, don't take the test, scroll down to bottom, click "grade my test'
Read only correct answers.cut learning curve in half.
With books same thing, read question, read answer paragraph, read correct answer. Learning rate more than doubled.
You don't befuddle your mind with 75% wrong info!!!
(3 out of 4 answers wrong or 75% wrong info and wasted time).
Learn more than twice as fast, much less confusion and mental effort.

Michael

Just so you know there it nothing different or special about a Gold Emblem TS-830 other than the gold lettered emblem on bottom of the VFO face plate instead of a Silver emblem.

Some believe it meant that rig came full filtered from the factory and some say had different Murata 455khz ceramic filter (K12 instead of K5), but the Murata 2nd IF filter change came in about the 3 million series and had nothing to do with being a gold emblem rig. The gold emblem did not introduce any circuitry changes or performance enhancements.

You will even find original 1 million series TS-830s that people have installed gold emblem VFOs in them. Almost impossible to tell an original Gold Emblem TS-830 unless you know someone who bought factory new one and has the original invoice to share with you and can tell you the year they bought it and the serial number.

Of course good to mention it when you go to sell the rig as the uninformed buyer might pay extra on ebay to get a gold emblem TS-830 thinking it represents some thing special.

First I'd like to thank you all for tolerating me (so far) and for the knowledge you have generously shared with me. I know your time is valuable, much more than so than mine and that most of the material I'm squeezing from you has been covered before at length.

I should, I geuss learn to search the archives to save you all the flustermation of my ignorance, confusions and diatribes.
What would be the fun in that? You Gentlemen would not get the satisfaction of leading a Newbie carefully through the learning curve and would not get the welcome break from the decades long task of the sometimes boring repetitive repairs.
Right?
(See, here I go again....).

I've got (5) TS-820S units now. Latest purchase came from California, kid couldn't sell it in 2 seperate week long sales attempts. Bid sales starting at $200 plus $40 shipping. I offered him $150 shipped he said he'd part it first, I showed him other "choppers" that weren't selling HARDLY ANYTHING in the last 2 weeks.
I offered him $200 shipped last week which he accepted.
Received yesterday.
Good job packing, 3 layers big bubbles and a tall stiff cup over the dial, good idea, a US flag sticker under my name and address label, nice touch.
He stuffed the remainder of the box with the "over pipe" type foam insulation, it performed well, never saw that before but it worked good.Single 3 layer box. Came in good condition through USPS in about 5-6 days from Cali to Missouri.

Radio is an old dog. Looks to have been stored in a basement or outdoor storage, quite alot of rust and lost case paint, exposed to moisture.
Display flickers alot at high end of dial. No transmit and sounds like some arcing.....
Meter stays up at 3db and no sig in receive in speakers.
Good parts radio candidate.
I think 3 Of my units do the flickering......

The radio presently being serviced, detailed (cleaned) was flickering and quit altogether last time on the bench. K4EAA pulls the VFO side cover and douses with Deoxit. I'd like to do more than that. While doing my brushing microsurgery on the RF board Wafers with it out of the radio, I am able to easily remove VFO side cover and almost stick my head into the VFO.
What is it in there that causes the problems?
I observe a leaf spring loooking copper 1/2" X 1/2" sheet metal curved piece on the back end of the variable cap center shaft.
Is this a mechanical electrical connection?
What needs cleaning and what causes the flickering display? I've scratched under the points where the "leaf spring" touches the shaft and where it touches the back wall of the shaft mount or chassis. Carefully bent it to add some arch, or spring tension, it seemed tired and not much spring or pressure against the shoulder on the shaft.
This display quit completely shortly after unit arrived. Alot of flicker then quit entirely.

I've tried swapping the entire "metel box" the display plugs into with a "known working" set from another radio, no change.
I pulled the front off that parts radio and pulled the tube display itself, plugged it into the board, no display, does it need to be well grounded? (I don't think so, the brackets that the display is mounted in are heavily black oxide coated, ground through wiring and board it plugs into I would assume).
I had been up for way too many hours (over 30 with the last 8 into the radio) and said that's enough for one day.
The box and set of boards I pulled have been removed from the metal box and I'm ready to do the "solder through board" connections repair. Holding board 1160 up to the light I see 15 of these "through board solder connections. Is 15 all of them?
On the 1150 board I'm not seeing any through board connections, correct?
Checking pins to board solder joints under magnification I find one loose pin, Pin 1, "CVC" on the portion of the board that protrudes through bottom of Chassis to lower part of radio.
I'll have to strip some insulated solid copper 22 gauge wire for now, to do the solder through board repairs. (just ordered some bare copper 22 gauge for these repairs on eBay).

So, questions are, what inside VFO is causing these problems, what is best way to fix, spray with Deoxit and pray?
Is there an easier way to remove Dig display other than pulling knobs and face? What a pain. (I did buy one casio calculator and have a bid on another to steal those displays)
I've had the vernier and all off down to the gears, how tough is it to get the VFO out of these old dogs? Pull that alumnum box and get at whatever is causing trouble easier and achieve a more permanent fix?
Am I right about that "leaf spring"? Is it a connection? or
what do I burn with my 15 gigawatt laser?
I'll get around to troubleshooting by checking what is supposed to be on what pins....only if I have to, after eliminating all mechanical issues, which I think ARE the VFO/display problems for the most part.
My initial understanding is that most display problems are in the VFO and most are cured by a good dose of Deoxit.
Gotta be a better solution than spray.....
Also aware the Modex plug for display is often troublesome.

Thanks beforehand Gentlemen,
Where do I send the check?
Michael///KD0WSJ

PS. This window (Post new Topic) functioned much better than the reply window....without the nauseating delays. Gotta be a better way without going to word or notepad.....WAIT!!! That's why all you guys do not have the previous messages when you post!! You are using a different route. You dogs. You let me suffer all this time.....

How about maybe introducing them to the Baofang type radios?
I dicussed with Mark Koernke on the microeffectlive.com this morning how the locals around here are using 462+ for local comms.
I bought a bao and a cheapy base 5db antenna. real impresed with it.
for $110 bucks not a bad setup. It is also monitoring the local sheriff and EMS.
Heard it can be setup to scan but I'm not that far in yet.
$40 for radio, $50 for ant, $20 for 18' of coax. Charger incl.
I like it.

Subject: Re: [TS-520_820_530_830] Hybrids: Store it or operate it?

Might I suggest that the kids of today will be much more inclined to stay after school and work on Arduino projects or perhaps a RTL2832U dongle.

SDR will much more interesting to the average kid. They like computers and software and would take to this easily.

Cost would also be much much lower than KW hybrids and more hands on participation at same time.

I cant even spell "I/Q" so I could not lead such a youth group.

My guess is already being done in some middle and/or high schools.

I love KW hybrids but just dont see the youth of today being lead to them in any number that would make a difference.

> Read only correct answers.cut learning curve in half.

Or maybe perhaps kinds could be you MIGHT want to study the theory and the rest of the information BEHIND the questions, learn what the whole thing is about, and THEN take the test for whatever level license.

I can get a ten-year-old with a good memory through the EXTRA exam, but GOD help that ten-year-old kid when an "I actually studied the information" General license holder asks him a question that isn't one of the test questions.

The IDEA behind having an EXTRA license in the first place was NOT to churn out a lot of people with that license. It was to give a nod to those of the amateur community whom were diligent and capable enough to learn all there was to know (or all they could, anyway) about the hobby.

I waited TWENTY YEARS as a Tech licensee, before I took the General and on a lark, the Extra tests, knowing I was going to pass the General, easily. Getting through the Extra exam missing only two questions SCARED THE CRAP OUT OF ME. All I could think of was NOW WHAT DO I DO? SOMEBODY'S GONNA FIND OUT I'M A FRAUD! I DON'T KNOW ALL THAT STUFF THAT WELL!

I didn't change my call when I got the Extra license, because I didn't want to advertise my un-earned "Biggest Pig, County Fair" Blue Ribbon.

What it HAS done has made me study my head off, and when someone does ask something, I dig in to it and work like a nut to find the answer for them. I don't feel that I have yet earned the chops that have always been given to Extra licenses. But I'm trying, because I don't want to let the side down.

Please reconsider, think about NOT doing an exam-cram.

It thins the blood.

46509. Recommended 'Classic' Keyer for TS-530S

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-19 12:32:15 UTC

Topic: 46509 Message: 46509

Hi to the group and Seasons Greetings

I would like to add a Keyer (either with or without integral paddles) to my Kenwood TS-530S and would prefer to search for something of the same era, early 1980s.
Is there a recommended Keyer for the TS-530S, perhaps a design classic of the times, with Negative keying like the TS-530S requires?

I've noted that within the photos section of this group that the Heathkit Keyer with integral paddle is shown on at least one photo - perhaps something along these lines.

Suggestions would be appreciated.

Thanks in advance and Merry Christmas.

Mick - M0GWD
Portsmouth, UK

46510. Re: [TS-520_820_530_830] Recommended 'Classic' Keyer for TS-530S

Topic: 46509 Message: 46510

Mick,

There are numerous keyers that will work with the KW hybrids. Below are a few keyers that I have used, including a couple of vintage "vacuum tuber" keyers.

MFJ 407B and 407D. MFJ has a series of CW keyers you can choose from, see their website for details on all models. Most all of MFJ's keyers have built in side tone oscillators that are adjustable in volume and tone, typically by front panel controls. Some MFJ keyers have an "internal" weight control that is accessible through a small hole on the cabinet or by removing the cabinet, while other MFJ keyers have the weight control on the front panel. The 407B and 407D can be powered by an external 12VDC power cube or by a 9 volt battery mounted internally. If you use a 12VDC power cube may sure you look at the brick. There are "AC" and "DC" cubes and if you apply 12VAC" to these keyers you can easily damage them. Also be aware that not all DC power cube's output voltage is regulated and will be exactly 12VDC. Unless the cube is a "regulated output voltage" power cube, the DC output voltages can be as high as "+19VDC".

Heathkit HD-10, Heathkit's first attempt at marketing a single lever non-Iambic keyer. The HD-10 keys negative "grid block" keying voltage up to -105VDC. The HD-10 has 3 controls, SPEED, WEIGHT, and VOLUME. The "WEIGHT" control is accessed through the screw driver slot on the top of the SPEED control knob using a small flat blade screw driver. Iambic paddles can be used with the HD-10 even though the HD-10 is not an Iambic keyer, they are connected to the terminal strip on the end of the keyer. I have an HD-10 that I use with my Heathkit HX-10 Marauder. The HD-10's side tone "frequency" is not readily adjustable without modifying the tone oscillator's circuit. The HD-10 has a built in 120VAC power supply.

Heathkit HD-1410 was Heathkit's first Iambic keyer with built in Iambic paddles. The HD-1410 can key both positive (+300VDC at 200ma) and negative (-200VDC at 10ma) by simply connecting the keyer to the transmitter using a 2 wire shielded cable. No internal jumpers to change. I use an HD-1410 with my Heathkit SB-400 xmtr. The HD-1410 does not have a weight control but it has front panel controls that adjust the "speed" (left control) and the side tone "volume" (right control). The "speed" control has a "Pull ON and Push OFF" switch that keys the "KEYER OUTPUT" socket on the rear panel. This is typically used for vintage transmitter tuning. The HD-1410 has a pot, accessed below the PC board (bottom half of the cabinet clam shell must be removed) that has a "limited" side tone frequency adjustment. The HD-1410 operates on either 120VAC or 240VAC, determine by jumper wires that connect the dual

primary 120VAC windings. These jumper wires are soldered so some soldering is required to change the primary voltage from 120VAC to 240VAC and vice verse. The HD-1410 can also be powered from an external 12VDC 100ma DC supply.

Heathkit SA-5010. This is a memory keyer with build in/slide in paddles. I have no experience with this keyer so I cannot comment on it's features and ease of use.

There are a few vintage "vacuum tube" keyers such as the Hallicrafters HO-1 and the Eico 717, both use a fast acting reed type relay to key the transmitter. Both have built in 120VAC power supplies and both have adjustable Weight, Speed, side tone frequency, and Volume controls. I use my Eico 717 to key my Heathkit Apache TX-1 that uses "cathode" keying. Cathode keying voltage can be approximately +130VDC which can give the operator quite a jolt. Not all modern keyers can accept/key cathode voltages at that level.

There are other keyers that you can use with the KW hybrid. The above keyers are the ones I have experience with and have owned.

Topic: 46509 Message: 46511

Mick,

If you decide on the Heathkit HD-1410, a good keyer, the complete assembly manual is available on the web at the following link

http://www.google.com/url?sa=t&rct=j&q=&esrc=s&source=web&cd=1&cad=rja&ved=0CCsQFjAA&url=http%3A%2F%2Ftubularelectronics.com%2FHeath_Manual_Collection%2FHeath_Manuals_H-HM%2FHD-1410%2Fhd-1410.pdf&ei=r_6yUoIUhKzbBY6qgcgE&usg=AFQjCNH2E8oSbqBdQjCxt7O-GzBKfwzXHw&bvm=bv.58187178,d.b2I

A 3.5mm stereo socket can be mounted on the HD-1410 keyer's rear panel and connected to the internal paddle terminals. This will give the operator the ability/option to use an external Iambic or non-iambic paddle with the HD-1410. It's an easy addition to the HD-1410 keyer. I like the HD-1410 keyer and use mine a lot.

Hello Mike, good morning

Thank you for the extensive reply. What a great group this is.
I do like the look of the Heathkit HD-1410 and it has good reviews on eHam too.
I'm not sure how many found there way to the UK though and were built as kits.

Having the option to power from 12V D.C. is good too, and as you say the A.C supply voltage can be changed for 240V, so I'll keep my eye open for those on sale both here and in the U.S.A.

This is exactly what I wanted Mike. Suggestions from someone with experience in using these keyers.
Also I've just picked up your other posting ref. the manual. Thank you.

All the best Mike and Happy Christmas from the UK.

Topic: 46509 Message: 46513

Mick,

You're welcome.

You can change the "range" of the "Speed" control by simply changing the value of resistor R9.

Speeds between 10 and 60 wpm - R9 is 5.6K 1/2 watt

Speeds between 10 and 35 wpm - R9 is 10K 1/2 watt.

I installed a 10K resistor for R9.

One word of caution I forgot to mention. The paddle travel is adjustable by removing the top cover (loosen the side screws), slide the top cover up, then loosen the paddle's black lever's hold down screw then move the black lever "left" or "right" to move the contacts farther apart or closer together. The Keyer's power cable should be "pulled" from the rear of the keyer BEFORE you attempt this mechanical adjustment as 120 or 240VAC is present near the lever and it's easy to receive a 120/240VAC electrical shock if you are not very careful.

Good luck searching the archives...This new NEO interface works wonders in 'searching'...Shortens the search time down to nothing....(That happens when one says, "Screw it!" I'll just ask the group.) <<GRIMACING>>

Anyone have any thoughts on why a VFO820 is not stable? My poor old, geezer fingers can't keep up with it when it starts to drift.....I am guessing leaky caps? Any other items to look at?

Thought I would reply to myself to resubmit my question.
If no replies I'll say shucky darn and figger it out on my own.
I'm good at that but I do like shortcuts.
Learning from others that have been down the road before me.
Might have to learn how to use the archive search.
Thanks ahead of time.

Subject: [TS-520_820_530_830] VFO and Display issues.

First I'd like to thank you all for tolerating me (so far) and for the knowledge you have generously shared with me. I know your time is valuable, much more than so than mine and that most of the material I'm squeezing from you has been covered before at length.

I should, I geuss learn to search the archives to save you all the flustermation of my ignorance, confusions and diatribes.
What would be the fun in that? You Gentlemen would not get the satisfaction of leading a Newbie carefully through the learning curve and would not get the welcome break from the decades long task of the sometimes boring repetitive repairs.
Right?
(See, here I go again....).

I've got (5) TS-820S units now. Latest purchase came from California, kid couldn't sell it in 2 seperate week long sales attempts. Bid sales starting at $200 plus $40 shipping. I offered him $150 shipped he said he'd part it first, I showed him other "choppers" that weren't selling HARDLY ANYTHING in the last 2 weeks.
I offered him $200 shipped last week which he accepted.
Received yesterday.
Good job packing, 3 layers big bubbles and a tall stiff cup over the dial, good idea, a US flag sticker under my name and address label, nice touch.
He stuffed the remainder of the box with the "over pipe" type foam insulation, it performed well, never saw that before but it worked good.Single 3 layer box. Came in good condition through USPS in about 5-6 days from Cali to Missouri.

Radio is an old dog. Looks to have been stored in a basement or outdoor storage, quite alot of rust and lost case paint, exposed to moisture.
Display flickers alot at high end of dial. No transmit and sounds like some arcing.....
Meter stays up at 3db and no sig in receive in speakers.
Good parts radio candidate.
I think 3 Of my units do the flickering......

The radio presently being serviced, detailed (cleaned) was flickering and quit altogether last time on the bench. K4EAA pulls the VFO side cover and douses with Deoxit. I'd like to do more than that. While doing my brushing microsurgery on the RF board Wafers with it out of the radio, I am able to easily remove VFO side cover and almost stick my head into the VFO.
What is it in there that causes the problems?
I observe a leaf spring loooking copper 1/2" X 1/2" sheet metal curved piece on the back end of the variable cap center shaft.
Is this a mechanical electrical connection?
What needs cleaning and what causes the flickering display? I've scratched under the points where the "leaf spring" touches the shaft and where it touches the back wall of the shaft mount or chassis. Carefully bent it to add some arch, or spring tension, it seemed tired and not much spring or pressure against the shoulder on the shaft.
This display quit completely shortly after unit arrived. Alot of flicker then quit entirely.
I've tried swapping the entire "metel box" the display plugs into with a "known working" set from another radio, no change.
I pulled the front off that parts radio and pulled the tube display itself, plugged it into the board, no display, does it need to be well grounded? (I don't think so, the brackets that the display is mounted in are heavily black oxide coated, ground through wiring and board it plugs into I would assume).
I had been up for way too many hours (over 30 with the last 8 into the radio) and said that's enough for one day.
The box and set of boards I pulled have been removed from the metal box and I'm ready to do the "solder through board" connections repair. Holding board 1160 up to the light I see 15 of these "through board solder connections. Is 15 all of them?
On the 1150 board I'm not seeing any through board connections, correct?
Checking pins to board solder joints under magnification I find one loose pin, Pin 1, "CVC" on the portion of the board that protrudes through bottom of Chassis to lower part of radio.
I'll have to strip some insulated solid copper 22 gauge wire for now, to do the solder through board repairs. (just ordered some bare copper 22 gauge for these repairs on eBay).

So, questions are, what inside VFO is causing these problems, what is best way to fix, spray with Deoxit and pray?
Is there an easier way to remove Dig display other than pulling knobs and face? What a pain. (I did buy one casio calculator and have a bid on another to steal those displays)
I've had the vernier and all off down to the gears, how tough is it to get the VFO out of these old dogs? Pull that alumnum box and get at whatever is causing trouble easier and achieve a more permanent fix?
Am I right about that "leaf spring"? Is it a connection? or
what do I burn with my 15 gigawatt laser?
I'll get around to troubleshooting by checking what is supposed to be on what pins....only if I have to, after eliminating all mechanical issues, which I think ARE the VFO/display problems for the most part.
My initial understanding is that most display problems are in the VFO and most are cured by a good dose of Deoxit.
Gotta be a better solution than spray.....
Also aware the Modex plug for display is often troublesome.

Thanks beforehand Gentlemen,
Where do I send the check?

Michael///KD0WSJ

PS. This window (Post new Topic) functioned much better than the reply window....without the nauseating delays. Gotta be a better way without going to word or notepad.......WAIT!!! That's why all you guys do not have the previous messages when you post!! You are using a different route. You dogs. You let me suffer all this time.....

46518. SV: SV: SV: [TS-520_820_530_830] TS830S no bias

From: Peter Ravn
Topic: 46257 Message: 46518

Mike,

Good news! My TS830S passed the first tests with driver and final tubes removed. No smoke or unusual sounds. Bias voltages run smoothly from - 40 VDC to - 110 VDC on FG. Screen voltages are + 265 VDC on SG. The panel meter works normally again, and so does the receiver. The next and final test will be with tubes installed.

I am waiting for the final cage kit from KE7OAY, and tomorrow I will have a new set of 6146B□s to replace the ones that turned RED. You stress that I should not reuse the same tubes. Why not?

Thanks a lot for your outstanding help.

Mike,

I found the smoking gun today: R102, a 10 k ohms resistor connecting Q10 on the AF unit to the FG terminal on the board. The resistor is severely discoloured, but surprisingly not open. It will naturally be replaced.

Mike,

I have ordered The Final Cage Repair Kit (C7, C8 and L1) from KE7OAY. When it is installed, and R11, R15 and R16 on the rectifier have been replaced, I will follow your instruction and let you know the result.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal

noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

Mike W5RKL

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

On 12/9/2013 4:29 PM, Peter Ravn wrote:

Mike,

After replacing R11 I had 264 DVC on the RF unit terminal, on terminals 210A and 210B on the rectifier and on SG on the final unit. After some time I managed to get 60 mA idle current and started tuning up. The transmitter seemed somewhat unstable, and the panel meter would not zero in STAND-BY. A scary noise was suddenly heard, whereupon the finals turned deadly red and the fuse on the rear blew. When I replaced the fuse and turned on the radio again, smoke came from somewhere between the AF and the RF unit. End of today.

Good night and good luck.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to

"hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73
Mike W5RKL

On 12/9/2013 1:49 AM, Peter Ravn wrote:

Mike,

There is no voltage on RF unit plug 9 pin2 (210A). On 210A on the rectifier there are 263 DVC, but zero on 210B, so where does that leave us?

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Emne: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Peter,

That's great to hear your 830 is coming back to life.

You said the plates turned RED in the 6146s. You don't know what damage may have occurred in the tubes when that happened. You said with the tubes removed there is no smoke and no unusual sounds. You also said the voltages are changing as they should when testing between receive and transmit, at least that is what I got out of what you said. Therefore, that's why I would not use the original tubes. It's also possible the original tubes themselves may have caused some or all of your problems.

Topic: 46520 Message: 46520

Hello all , got the "tune" issue fixed, broken D1 on CAR-2 unit. Now the issue is that 28 MHz is at 22 MHz and the freq readout from the VCO is 31 MHz so 5 MHz low??? Have looked on the VCO board and the PD board for bad parts but cannot find any. Even replaced D20 and D21 on the PD board as a test. This changed nothing. Wondering if the "5 MHz" issue is on the PD board or somewhere between the carrier mixer or the VFO since they are 5.5~5 MHz links. Any ideas?

Thanks

Tom Jones N8NMA

Here's a variant on this problem: when returning from transmit, the receiver loses several S-points of sensitivity. It seems to affect all bands that I use. Now I have a rotator controller nearby, and if I momentarily flick the motor current, it's enough to "reset" the receiver to normal sensitivity. It's as though the motor cable transient induces a spike in the receiver front end that somehow offsets a charge somewhere.

I use a linear, but this problem occurs whether the linear is operating or not.

I have been advised about an inductor that normally shorts dc to ground which could be the culprit if it's gone open. Any thoughts about this one?

Try gently tapping on the Aux relay on the Audio board. This relay among other things switches the operating bias for front end RF amp Q1.

Can also monitor the bias voltage at RF board on Conn 8 Pin 2 RB1. Should see approx -3.3vdc in TX and approx +1.1vdc in RX mode.

Can also gently wiggle molex Conn 8.

The aux relay is commonly the problem. I have not had luck trying to clean the contacts. I recommend buying a sub relay from Ken K4EAA while they are still available.

I forgot to mention I dont know who is telling you about a choke that shunts dc to ground and causing your problem. I suspect he may be talking about L5 470uhy choke at output of the Pi-network?

That choke is often referred to as the "safety" choke as it will prevent 900vdc anode voltage from appearing at the SO-239 connector and on the antenna and your fingers in event that C7 blocking/coupling cap should short. You would not want to be attempting to connect a PL-259 if there was 900vdc present!

This choke also serves as a DC return so that C1 tank cap and C2 load cap do not charge to anode dc level and see the capacitor plates arc over.

If L5 goes open it should have no effect on your receiver sensitivity.

Ask this fellow to tell you specifically which choke he suspects is causing receiver de-sensitivity.

Lastly, if you find you have good RB1 TR transition then check DRB at same Conn 8 on RF board as it is also switched by the Aux relay contact and if Driver tube isnt being biased off completely could also cause RX desens.

I -- and many others -- have experienced the same problem. In my case,
the easily accomplished replacement of RL1 on the audio board cured it.

Jim Showker has a nice presentation on relay issues posted here:

A variant on this is that my TS830S loses several S-points of sensitivity when returning to receive from transmit. Now I have a rotator controller nearby, and if I pulse the motor once, it seems to reset the receiver to normal. It's a bit annoying having to do this almost every over sometimes. It's as though the rotator cable transient induces enough in the receiver input to cancel a built-up charge and return some circuit to normal (MOSFET bias circuitry?). It seems to occur across all the bands that I use.

Any ideas as to what the problem might be?

Thanks.

It sounds like you are losing VFO input to the PLL board. Can monitor VFO signal level at PLL board Conn 5 Pin 2. It should be approx 200mv rms rf volts.

This causes loss of VCO signal to the RF board which means no 8.830mhz RIF signal so no RX just noise. You can monitor VCO level at TP-3 on the RF board near the VCO plug. Test point looks like a small vertical mounted resistor. Should see minimum of 1.0 rms rf volts at TP-3.

One cause of this is dirty mini-din switch contacts in the Remote VFO jack on rear panel. Need to clean with Deoxit and exercise the switch by inserting and removing a din plug multiple times.

Topic: 46087 Message: 46537

Hi,

I've been reading this news group for about a year, after purchasing an 820S that needed work. There is a gold mine of info here from a great group of people that has been most helpful. I've since re-capped the HV section and most of the boards. The HV re-cap made the biggest difference, no more voltage sag on key down and it's working at full power out.

Here is my question to this knowledgeable group. The circuit diagram/PC Board layout on page 56 of the Service Manual shows a 1uf 50V (C38) electrolytic capacitor but it is not installed on the circuit board. Which is correct, the diagram or my unit?

While the 820 works well, my curious side thought about installing the cap (the board has the location marked) to see what, if any, difference it would make. Possible that a manufacturing update was incorporated but failed to make the update to the manual. Any opinions?

The soldering iron is hot and ready. J

Every person who applies for membership to this group and when their membership application is approved, receives a message explaining this very subject. The message clearly states that every new members is "Moderated" and the new member's messages must be approved by a Co-owner or Moderator before they are sent on to the group's message server for dissemination to all members.

For those new members who, for what ever reason, did not take the time to read that message, here is the segment of that message that outlines this subject:

"/*New member posts will be "moderated." This means that; your posts/messages will be reviewed and either approved or disapproved, by a Group Co-owner or Moderator PRIOR to being sent to the groups main message area.*//*How long this "moderation" last is up to you. The more active you are(numerous posts..etc.)*//**//*and your ability to "play by the rules", your "moderation time" will be short.*//*"*//*
*/

You can read the entire message that was sent to you and all new members by simply logging onto the group's homepage then click on "Files". The message is located in the group's "Files" section under "AUTOTEXT MSGS". The message is titled "Message on Approved Membership".

I will need to examine the schematic for a a detailed explanation. However, I just thought that my case would possibly save some troubleshooting time. The symptoms were exactly the same. In fact, when I rocked the bandswitch ever so gently, or put the heater switch in the on position, the display would light up and sound would return! There was something mechanically intermittent. I replaced the coupling and gave the bandswitch a good cleaning resulting in perfect operation. I stumbled upon a webpage that showed some common TS-530 issues, and that is what led me to the bandswitch coupling. The wafers were not engaging in unison.

Please excuse me if I ventured a response without a complete electronically based rationale. I will consult the schematic to attempt an explanation for what I observed empirically. (I'm new, so thanks for your patience.)

I will have to look at the schematic in order to justify the relationship, but I did experience the same symptoms until stumbling upon this webpage: http://www.k4eaa.com/examples.html. The hint for me was the fact that if I were to very gently rock the bandswitch, the display would go out just as it often did when the receiver was cold. It turned out that all contacts on the wafers were not engaging in unison. I replaced the coupling and cleaned the switch, resulting in perfect performance once again.

Please excuse if my answer was incomplete due to a lacking electronic rationale. I just described what happened in my case, thinking it could save kd8hmo some time. I felt it was potentially related due to very similar symptoms. I will head to the schematic for a more precise explanation.

Mike,

I had carefully followed your instructions and was now ready for the final test with a new set of 6146s plugged in. When I was adjusting the bias with the pot on the rear panel, there was a hardly audible crack. The meter said 60 mA, when I turned off the radio and started looking for a cracked resistor. I found none, so the crack might have come from somewhere else in my room. But when I resumed the bias adjustment, there was instantly a loud crack and a flash. I powered off the 830s immediately.

Upon closer inspection four cathode resistors on the final unit board were open. They had worked as fuses and hopefully saved the finals. In the morning I had replaced the old cathode resistors with new ones with the same specs, so why did they open?.

Peter,

That's great to hear your 830 is coming back to life.

You said the plates turned RED in the 6146s. You don't know what damage may have occurred in the tubes when that happened. You said with the tubes removed there is no smoke and no unusual sounds. You also said the voltages are changing as they should when testing between receive and transmit, at least that is what I got out of what you said. Therefore, that's why I would not use the original tubes. It's also possible the original tubes themselves may have caused some or all of your problems.

Mike W5RKL

On 12/19/2013 12:32 PM, Peter Ravn wrote:

Mike,

Good news! My TS830S passed the first tests with driver and final tubes removed. No smoke or unusual sounds. Bias voltages run smoothly from - 40 VDC to - 110 VDC on FG. Screen voltages are + 265 VDC on SG. The panel meter works normally again, and so does the receiver. The next and final test will

be with tubes installed.

I am waiting for the final cage kit from KE7OAY, and tomorrow I will have a new set of 6146B□s to replace the ones that turned RED. You stress that I should not reuse the same tubes. Why not?

Thanks a lot for your outstanding help.

Mike,

I found the smoking gun today: R102, a 10 k ohms resistor connecting Q10 on the AF unit to the FG terminal on the board. The resistor is severely discoloured, but surprisingly not open. It will naturally be replaced.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

Mike W5RKL

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the

final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is

pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

Mike W5RKL

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias

voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up

to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73
Mike W5RKL

On 12/9/2013 1:49 AM, Peter Ravn wrote:

Mike,

There is no voltage on RF unit plug 9 pin2 (210A). On 210A on the rectifier there are 263 DVC, but zero on 210B, so where does that leave us?

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend

you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Emne: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Mike,

I followed the standard procedure. I turned the POWER and HEATER switches on, placed the MODE switch to SSB, the METER switch to lp, pushed the SEND button and adjusted the BIAS control, but there was no reading at all. I then measured pin 5 in in the finals and saw no voltages in STAND-BY or SEND

position. The only deflection on the TS meter is in HV in SEND position with voltages about 820 DVC.

A correction to my first mail. I do hear the t/r antenna relay when I key the transmitter.

Emne: Re: [TS-520_820_530_830] TS830S no bias

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

73
Mike W5RKL

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

If you install C38 you will change the ALC release or recovery time constant. It will lengthen the time it takes for the 3.5vdc ALC bus voltage to come back up to normal between words and syllables.

KW experimented with different AGC and ALC RC time constants in the 820 and other hybrids by installing or switching in different capacitors.

KW uses the ALC as form of compression by changing the time constants in SSB mode. Has very fast attack time and slower release or recovery time.

As part of the QRO mod sometimes people install different caps to shorten the delay or release time to increase average to peak output power ie get more talk power without regard for splatter.

I would leave C38 out as your rig has a good speech processor if needed and it uses RF negative feedback to improve linearity so the ALC time constant as is works in concert with that feature and if you adjust mic gain properly will have nice clean signal.

By the way when recapping these hybrid rigs you have to be careful not to lift a foil and have to observe how each cap is installed in the board. There are mistakes on the schematics and board silk screening. If you find a electrolytic that is installed reverse polarity make sure you study the circuit and dont automatically assume the as built config is wrong and reverse the replacement cap. You can shorten the life of that new cap.

Michael:

You posted that you had already used a metal instrument inside the VFO to modify the rotor shaft wiper contact by attempting to bend it. That is a "ham-fisted" thing to do and I have no idea what would prompt any tech to do that. I have even see some hams recommending that you solder a coax braid shield pigtail lead to this contact. Cardwell and others abandoned that approach and shaft brushes many years ago.

The rotor shaft wiper contacts in all the Hybrid air variable capacitors (depending on the cap and function will find more than one wiper) are made of phosphor bronze which have very high conductivity and are self-lubricating. They have been heat treated to have the proper spring temper.

The fingers run against a machined face on the end of the rotor shaft. No reason to suspect this wiper contact has lost its temper and need to bend it before doing proper cleaning.

The purpose or this contact is so that the RF current has a very low resistance path to circulate back and forth from the fixed to rotating plates. Without this contact arrangement the current would have to flow thru the rotor shaft bearing ball and race assembly which is not a good low resistance rf contact.

So with age as this contact darkens brown/black and maybe with traces of green oxide you need to apply Deoxit sparingly with an artist brush or tooth pick and exercise the rotor thru its complete range end to end. Common to have to do that multiple times. However, never never poke around or try to bend this contact. Also do not lubricate it with WD40 or any type of grease. You dont want grease or oil to migrate between contact finger face and shaft shoulder surface and introduce resistance.

As to cause and effect I dont know why you think you have a VFO problem? As I understand it you removed the RF board and began contact cleaning and I am not sure what TX or RX operational issues led you to diagnose bad bandswitch contacts?

Usually two operational issues with VFO. 1. Long term drift outside of spec OR 2. Output drops out or jumps in and out as turned thru its range.

Drift outside normal short term warm up drift and long term drift is usually caused by drift in the 9vdc regulated supply or a change to temp compensating capacitors in the VFO LC circuit. Cleaning the rotor wiper contact wont fix this. Using a remote VFO or powering the internal VFO with a fresh 9vdc battery will confirm or eliminate if the 9vdc regulated supply is causing the drift. The regulator is located on the AF-AVR board.

VFO frequency jumping or VFO rf output level coming and going is usually due to dirty rotor contact wiper. This assumes that you are losing the VFO output signal at the VFO and not in its path to where it is used. There are some places such as 8/9 jumper, molex connectors, and mini- din switches in KW hybrids which can be cause of loss of VFO signal where it is needed. For example if you lose the VFO signal to the PD you will get an unlock and blank the display. Measuring with RF millivolt meter or O-scope at the PD board will tell if VFO

signal is there consistently and at correct level.

The Service manual has a pretty good description of how the PLL functions.

Lastly, if you Google on 820 digital display problems you will find lots of info on resoldering all the connections on the counter mixer and counter unit boards and placing wires thru the vias.

That is the best I can do for you.

Topic: 46527 Message: 46546

The S22 switch inside the PA cage selects the correct tank coil tap and correct padder caps for resonance on the selected bands. It must be synchronized with the TX Mixer and Drive stage tuned circuits that are switched in by the S1-4 and S1-7 band switch wafers on the RF board.

When you get these two shafts out of sync due to slippage in the white nylon coupler the result can be 6146 finals damaged due to high off resonance plate current.

As to your receive coming and going as you gently rock the bandswitch knob back and forth or turn the heaters on and off. You may have a bad/dirty molex connector contact on the RF board. Kind of unusual for touching the band switch knob to cause enough movement in the RF board to make this connection come and go. This is not what you saw.

Turning on the heater switch can produce minor physical vibration and some momentary voltage drop. Perhaps there is a momentary problem with bias voltage switching for the RF amp and/or Driver tube. You may also have a dirty VCO connector/plug interface on the RF board that is being disturbed.

I suspect you were not just rocking the bandswitch knob which is the normal way to feel for dead band or free play in the switch which is clear indication you have cracks at the set screw area which allow the two shafts to get out of sync.

The correlation between rocking the bandswitch knob or the cycling the heater switch that causes the receiver to go dead and the display to blank can be related to bandswitch deck S1-1 on the RF board. If you move the bandswitch knob off one detent and move it a couple of degrees between detents then you will of course cause the display to blank and the receiver to go dead. So what you have to do for example is move the bandswitch between 3.5 and 7 and receiver will go dead and display will blank.

This normally takes more knob rotation than just checking the dead band or free play. It requires moving the bandswitch to get the switch wiper to be between contacts. If the coupling to S22 is very loose then its shaft wont turn with the shaft from the knob and you will lose the normal band specific detent positions as the detent balls are located on S22.

What causes the display blanking is you have disrupted the 9vdc bias voltage to the diode switching matrix at S1-1 which provides bandswitch position information to the PLL. PLL will unlock.

So was not trying to give you a hard time. Any KW hybrid can be made to exhibit the operational issues you describe if you turn the bandswitch knob far enough between the normal band select detent positions.

Thanks Mike.
I did read it when first joining, reread it yeaterday when looking throught the files. Read it again now.
Lack of sleep, long hours, too many tasks make me mentally sluggish.
(I'm s l o w anyhow....)
Working in my greenhouse, prepping for wood stove there, Ice on antennas this morning, eBay buiseness, not much time left over for radio troubleshoting.
Haven't touched the 820Sugar with VFO/display issues for 2 days......
Haven't received any advice either.
Spent 3 hours on the groups' page yesterday, mostly downloading files I didn't already have.
Don't have time to go through voluminous monthly files to find VFO/display titles....Or time do work on a radio right now. Took down my sweet fan dipole this morning, removed ice from G5 and Swedish dipoles. Gonna have to do that again this afternoon. May just leave them down till ice storm in SW Missouri is over.
Then, IF I still have electricity this evening, I MIGHT get to work on the radio again....

Is there a way to search those files?
I'm not seeing one.
Michael///KD0WSJ

Peter,

You should first think what "difference" or "change" has occurred since you replaced the 4 cathode resistor then performed the voltage measurements/test? The only change you have indicated is you replaced the 6146B final tubes. Yes, I said I didn't trust the original tubes, still don't, but now I don't trust the replacement tubes you used either! I suspect there are possibly shorts in the replacement 6146Bs which caused significant increases in voltage, current, and power dissipation in the cathode circuit with the replacement 6146Bs installed.

You should understand the 6146 has a "Beam Forming" plate that is connected both internally AND externally to the tube's "Cathode". This is required so the Beam Forming plate has the same potential as the Cathode, "negative in respects to the plate". So any short to the Beam Forming plate is also a short to the Cathode.

You can perform the calculations yourself, to see what happens when element short internally in the tube. All the voltage and resistance values you need to perform the calculations are shown on the final amplifier's schematic. The following is an example if a short occurs between the 6146 screen and beam forming plate/cathode and it clearly shows what voltage, current, and power values will be in the final amplifier's cathode circuit.

For example, if the screen shorts to the beam forming plate, the cathode voltage would "instantly" become "+265VDC" which will result in "53 amps" of cathode current (265 / 5 = 53) and 14,045 watts dissipated in the cathode circuit (53 x 53 x 5 = 14045)! That would result in 13.25 amps flowing through "each" 20 ohm 1/2 watt cathode resistor (265 / 20 = 13.25) and each cathode resistor dissipating 3,511.25 watts (13.25 x 13.25 x 20 = 3511.25).

Could you post a link to that web page with KWTS-530 fixes?

TNX,
Michael///KD0WSJ

Subject: [TS-520_820_530_830] RE: New Problem With TS-530S

I will need to examine the schematic for a a detailed explanation. However, I just thought that my case would possibly save some troubleshooting time. The symptoms were exactly the same. In fact, when I rocked the bandswitch ever so gently, or put the heater switch in the on position, the display would light up and sound would return! There was something mechanically intermittent. I replaced the coupling and gave the bandswitch a good cleaning resulting in perfect operation. I stumbled upon a webpage that showed some common TS-530 issues, and that is what led me to the bandswitch coupling. The wafers were not engaging in unison.

Please excuse me if I ventured a response without a complete electronically based rationale. I will consult the schematic to attempt an explanation for what I observed empirically. (I'm new, so thanks for your patience.)

Topic: 46087 Message: 46550

Thanks for the info, Terry.

The pads for C38 are solder filled, doesn’t look like a component was missed so will leave it as is. Two more boards to recap (IF X48-1150 and FIX-VOX X50-1350). I’m moving on to the VOX board. When pulling a cap, I check it against the schematic and have not found any discrepancies so far. While desoldering a component using a desoldering wick, one of the pads lifted. Fixed it by bending the new component leg down on the trace to keep it from moving and breaking off. I’ve also been reflowing the dubious solder connections I’ve noticed in this old rig. The radio is tested after each board is recapped so that I can narrow down any problems that may arise. No problems so far. The biggest difference was after replacing the HV caps. No more HV sag on key down and RF output is much higher, near 100W. Planning to finish with this over the weekend, in time for the RAC Winter Contest, December 28.

73, Nick

Mike,

I did perform voltage test after I replaced the four cathode resistors. Voltages were according to specs. Then I plugged in the new final tubes. Again bias and screen voltages on FG and SG on the final unit board were according to specs. Then I switched on the HEATER and after a few minutes the SG SWITCH as well. Voltages still normal, no smoke, no unusual sounds. It was not until I keyed the transmitter and started the standard bias adjustment procedure that the cathode resistors opened. I did no more than that.

The finals (6146W JAN) were shipped from RF parts through a local shop and arrived yesterday. They are unused/new and quite expensive. If they are bad and have shorts, I will naturally lodge a complaint. But how to prove they were bad on arrival?

Peter,

You should first think what "difference" or "change" has occurred since you replaced the 4 cathode resistor then performed the voltage measurements/test? The only change you have indicated is you replaced the 6146B final tubes. Yes, I said I didn't trust the original tubes, still don't, but now I don't trust the replacement tubes you used either! I suspect there are possibly shorts in the replacement 6146Bs which caused significant increases in voltage, current, and power dissipation in the cathode circuit with the replacement 6146Bs installed.

You should understand the 6146 has a "Beam Forming" plate that is connected both internally AND externally to the tube's "Cathode". This is required so the Beam Forming plate has the same potential as the Cathode, "negative in respects to the plate". So any short to the Beam Forming plate is also a short to the Cathode.

You can perform the calculations yourself, to see what happens when element short internally in the tube. All the voltage and resistance values you need to perform the calculations are shown on the final amplifier's schematic. The following is an example if a short occurs between the 6146 screen and

beam forming plate/cathode and it clearly shows what voltage, current, and power values will be in the final amplifier's cathode circuit.

For example, if the screen shorts to the beam forming plate, the cathode voltage would "instantly" become "+265VDC" which will result in "53 amps" of cathode current (265 / 5 = 53) and 14,045 watts dissipated in the cathode circuit (53 x 53 x 5 = 14045)! That would result in 13.25 amps flowing through "each" 20 ohm 1/2 watt cathode resistor (265 / 20 = 13.25) and each cathode resistor dissipating 3,511.25 watts (13.25 x 13.25 x 20 = 3511.25).

On 12/21/2013 7:26 AM, Peter Ravn wrote:

Mike,

I had carefully followed your instructions and was now ready for the final test with a new set of 6146s plugged in. When I was adjusting the bias with the pot on the rear panel, there was a hardly audible crack. The meter said 60 mA, when I turned off the radio and started looking for a cracked resistor. I found none, so the crack might have come from somewhere else in my room. But when I resumed the bias adjustment, there was instantly a loud crack and a flash. I powered off the 830s immediately.

Upon closer inspection four cathode resistors on the final unit board were open. They had worked as fuses and hopefully saved the finals. In the morning I had replaced the old cathode resistors with new ones with the same specs, so why did they open?.

Peter,

That's great to hear your 830 is coming back to life.

You said the plates turned RED in the 6146s. You don't know what damage may have occurred in the tubes when that happened. You said with the tubes removed there is no smoke and no unusual sounds. You also said the voltages are changing as they should when testing between receive and transmit, at least that is what I got out of what you said. Therefore, that's why I would not use the original tubes. It's also possible the original tubes themselves may have caused some or all of your problems.

73
Mike W5RKL

On 12/19/2013 12:32 PM, Peter Ravn wrote:

Mike,

Good news! My TS830S passed the first tests with driver and final tubes removed. No smoke or unusual sounds. Bias voltages run smoothly from - 40 VDC to - 110 VDC on FG. Screen voltages are + 265 VDC on SG. The panel meter works normally again, and so does the receiver. The next and final test will be with tubes installed.

I am waiting for the final cage kit from KE7OAY, and tomorrow I will have a new set of 6146B□s to replace the ones that turned RED. You stress that I should not reuse the same tubes. Why not?

Thanks a lot for your outstanding help.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

Mike W5RKL

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal

noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

Mike W5RKL

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to

"hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Emne: Re: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no screen voltage to the driver and both final tubes.

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Mike,

A new careful measurement gave another result. On the rectifier there are ☐ 109 DVC in STAND-BY and ☐ 107 DVC in TUNE. On pins 5 of the final unit there are ☐ 96 DVC in STAND-BY and ☐ 57 DVC in TUNE. So apparently there is a loss, but not a complete loss of bias voltage, which might prove fatal.

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

On 12/8/2013 9:15 AM, Peter Ravn wrote:

Mike,

I followed the standard procedure. I turned the POWER and HEATER switches on, placed the MODE switch to SSB, the METER switch to lp, pushed the SEND button and adjusted the BIAS control, but there was no reading at all. I then measured pin 5 in in the finals and saw no voltages in STAND-BY or SEND position. The only deflection on the TS meter is in HV in SEND position with voltages about 820 DVC.

A correction to my first mail. I do hear the t/r antenna relay when I key the transmitter.

Emne: Re: [TS-520_820_530_830] TS830S no bias

Peter,

You said you checked for bias voltage and found none. If I may ask, did you measure the bias voltage at the final tube grids, pin 5, and that is where you found no bias voltage?

73
Mike W5RKL

On 12/8/2013 2:15 AM, ravnpeter@... wrote:

There is no current in TUNE position on my TS830s. In SEND position there is no deflection on the meter and no noise from the t/r relay. The heater and SG switch are naturally on.

I checked R15 in the rectifier, and it was okay. So were the cathode and plate resistors in the final unit. I then checked the bias and found no bias at all. Adjusting the the BIAS control had no effect.

Any advice will be appreciated.
Thanks.

Be very careful executing any of the advice found on any of these mod or service bulletin sites. Really need to study all and see if there is sound technical basis.

Much bad and flat wrong info to be found. There is no reason to place a star lock washer on every board hold down screw! This is fairly benign recommendation and others not so much so.

Most of the service bulletins are really "psuedo" service bulletins that just contain long lists of one line entries that are owner provided fixes. No 21 bulletin is one of the worse that has you essentially replace all active devices anytime you have a receiver or transmitter issue.

There is a very bad one for the TS-530 that has you replace TIF amp mosfet and S-meter FET due to nearby lightning or ESD (high voltage transients at the antenna) coming thru the Pi-network and FG line back to the ALC bus. They even added a VDR to the FG line on the audio board to suppress this. This is silliness. No way for ESD to come back to the ALC bus thru the 6146 control grids to the FG line.

This is classic case of mistaken cause and effect correlation.

What really happened was a 6146 arc over. Normal arc over occurs from Anode to Cathode and seldom affects the control grid. Beam plates are physically closest to the anode.

You will notice that the TS830 which is the same circuit as the TS530 that the VDR on the FG line has been removed and no such recommendation to mod the TS830.

I have had more than one fellow tell me how they replaced the TS530 TIF amp mosfet and S-meter FET based on this KW mod only to find it did not restore the receive function.

So OK to collect up all the KW documentation that you can, but strongly recommend that you read these things and put on your thinking hat before executing any of them.

I dont want to jump in on Mikes thread. Will just offer that I also buy and use 6146W JAN (Sylvania) finals from RF Parts Co. and yes expensive state side so imagine even more expensive for you. I have had very good experience with them.

My experience with RF Parts is that they will replace defective tubes without much fuss. Even if NOS it means they are still 30 plus years old so have been sitting on the shelf off gassing and perhaps ingress around the pin seals? You might write Tom Rauch W8JI. He purchased the Sylvania JAN 6146Ws in carton lots years ago and he tell me he experiences a level of failure with these tubes when he performs hi-pot screening before installing in his many 6146 vintage rigs. I cant recall the exact percentage that wont hold off even 1500 vdc. I think you can get his email address off QRZ.

As I mention probably one of best ways to tell is to DC hi-pot all 6146 finals before installing and most hams have no access to a hi-pot. Good tube should hold off 2000 to 2500 vdc. Tubes see approx 1600 volts swing in service.

One last thing are you 125% certain you have no bad spot on the bias voltage adjust pot? Loss of bias voltage can cause thermal runaway and tubes to glow red. However, I have never experienced blown cathode resistors due to thermal runaway. Not saying it cant happen. I just have never experienced it.

My money is on arc over that Mike explained in his response to you.

Good luck.

Thank you Sir, that bunch of info is more than I would have deduced in 40 hours. It's what I wanted and needed. Yes the wiper had corrosion and yes had almost no temper or contact pressure. In fact there was a 1/32" gap....away from the contact shoulder and I think it appeared to have been lubed.
The display had flicker and had quit last time I tried to use the radio. No other history, I didn't have any Knwds before September, now I have 8.

There were no issues with wafer switches. I did not diagnose bad wafer contacts.
Perhaps I have exceded the level of "Golden Screwdriver" to a new level of "Golden Hemostat"

I'm attempting Preventive Maintenance. When I finish my "unnessary maintenance" on the wafers they look new (the ones I can get at).
I did damage two of the contact fingers on one of the first radios, "Old Dog", the one with bad soldering, unhooked wiring, burned rf and rectifier baoads...and (10) 33 ohm resistors instead of (4) 20's......5 hours doing microsurgery to use 22 gauge sterling silver wire and silver solder to repair damaged wafer finger contacts
I won't make that mistake again.

From what I have gleaned since joining you wonderful Gentlmen most if not all of you prescribe to the theory of "if it ain't broke, don't fix it". While generally I can agree with this I'd like to go beyond that myself. These rigs are 35 years old. Just spraying them with deoxit may keep them going for awhile, but the way things are going I don't see us being able to buy a new can of deoxit next year.....
I'd like to think that I'll get another 10-20 years out of mine because I went beyond the "spray and pray" method.....We'll see, I plan to live well beyond 100.

I have an idiosyncracy in that I try to redesign or re-engineer EVERYTHING, always have. Sometimes it's a Blessing, sometimes it's a curse.
I won't give the voluminous history of figuring out things on Turbine jobs engineers had given up on, or how many of my patent ideas have been stolen because I couldn't "keep my mouth shut", (some were thought up by others during same time period, coincidence).
Not saying much there, many of the engineers I've met are real dimwits.

Based on past my performance of modifications and untraditional redesigns and repairs of everything from chainsaws to tractors, hydraulics and electromechanical devices, even moster trucks to motorcycles, since early childhood, I am confident that my fresh ideas will produce excellent results.

Time will tell if I'm as sharp as I think I am and extending the life span of the rigs or producing
"badly damaged parts radios"!.....hi....hi....
I consider myself a mechanical genius, I have been tested 3 times, 99.9 percentile, tests were therefore inadequate to measure abilities.
 I think in mechanical ways, does that make sense?

I'm somewhat of an idiot Savant, just leave out the Savant part sometimes!!

"Ham fisted" HAH!! That's funny.

I understand the undesired curent path through bearings, it has been a problem with motor designs for over 100 years.
Or welding when a shaft supported by bearings is involved, welding current passing through bearings, damaging them, from a ground cable misplaced.

What is "PD"?
Vias? Is that correct terminology for 2 sided board?

I will do a Google search for VFO and display info, thank you, I forget sometimes this computer has amazing knowledge resources.

Is there no search feature to peruse the monthly records of this groups' history? I didn't see a way, other than scanning all the titles and haven't had the time yet.
Which I assure you all I will be doing as time permits.

I have had difficulty remembering what conditions exist in what radios. I have been taking detailed notes and numbering the rigs to alleviate this problem

Thank you for your valuable time and advice Terry.
I appreciate it more than you will ever know.

Everyone have a super weekend!

"Once it starts Communications will be vital"

Subject: Re: [TS-520_820_530_830] My post

Michael:

You posted that you had already used a metal instrument inside the VFO to modify the rotor shaft wiper contact by attempting to bend it. That is a "ham-fisted" thing to do and I have no idea what would prompt any tech to do that. I have even see some hams recommending that you solder a coax braid shield pigtail lead to this contact. Cardwell and others abandoned that approach and shaft brushes many years ago.

The rotor shaft wiper contacts in all the Hybrid air variable capacitors (depending on the cap and function will find more than one wiper) are made of phosphor bronze which have very high conductivity and are self-lubricating. They have been heat treated to have the proper spring temper.

The fingers run against a machined face on the end of the rotor shaft. No reason to suspect this wiper contact has lost its temper and need to bend it before doing proper cleaning.

The purpose or this contact is so that the RF current has a very low resistance path to circulate back and forth from the fixed to rotating plates. Without this contact

arrangement the current would have to flow thru the rotor shaft bearing ball and race assembly which is not a good low resistance rf contact.

So with age as this contact darkens brown/black and maybe with traces of green oxide you need to apply Deoxit sparingly with an artist brush or tooth pick and exercise the rotor thru its complete range end to end. Common to have to do that multiple times. However, never never poke around or try to bend this contact. Also do not lubricate it with WD40 or any type of grease. You dont want grease or oil to migrate between contact finger face and shaft shoulder surface and introduce resistance.

As to cause and effect I dont know why you think you have a VFO problem? As I understand it you removed the RF board and began contact cleaning and I am not sure what TX or RX operational issues led you to diagnose bad bandswitch contacts?

Usually two operational issues with VFO. 1. Long term drift outside of spec OR 2. Output drops out or jumps in and out as turned thru its range.

Drift outside normal short term warm up drift and long term drift is usually caused by drift in the 9vdc regulated supply or a change to temp compensating capacitors in the VFO LC circuit. Cleaning the rotor wiper contact wont fix this. Using a remote VFO or powering the internal VFO with a fresh 9vdc battery will confirm or eliminate if the 9vdc regulated supply is causing the drift. The regulator is located on the AF-AVR board.

VFO frequency jumping or VFO rf output level coming and going is usually due to dirty rotor contact wiper. This assumes that you are losing the VFO output signal at the VFO and not in its path to where it is used. There are some places such as 8/9 jumper, molex connectors, and mini- din switches in KW hybrids which can be cause of loss of VFO signal where it is needed. For example if you lose the VFO signal to the PD you will get an unlock and blank the display. Measuring with RF millivolt meter or O-scope at the PD board will tell if VFO signal is there consistently and at correct level.

The Service manual has a pretty good description of how the PLL functions.

Lastly, if you Google on 820 digital display problems you will find lots of info on resoldering all the connections on the counter mixer and counter unit boards and placing wires thru the vias.

That is the best I can do for you.

Peter,

The only "new" 6146" vacuum tubes I know of that are being manufactured "new", come from China. It is quite possible the 6146Ws you received from RF Parts were made in China.

I have no experience with RF Parts vacuum tubes. I have been buying all my 6146 tubes from:

www.vacuumtubes.net

I have never received a bad tube from them. I recently purchased six 6146A that were installed in my Heathkit HW-101, SB-100 transceivers and SB-400 and SB-401 transmitters. None of them have failed and are still being used today at full output. The HW-101 sat for "20 years" in the owner garage. After a lengthy time period of cleaning testing, etc, the "original" 6146As produced 100 watts output for "4 days" and on the "5th day" one of the 6146As "arced" causing the HP-23 power supply breaker to trip. The breaker tripping prevented the "2.2 ohm 2 watt" cathode resistor from failing due to the high current flowing in the cathode circuit. If the breaker would not have tripped, I suspect the 2.2 ohm 2 watt cathode resistor would have failed, permanently damaged!

Speaking of a breaker tripping, did the fuse blow in the 830 when the problem occurred? If it didn't. why didn't it? Was the fuse rating wrong? The fuse should have blow with that high current flowing in the cathode circuit!

I would write and ask RF Parts, informing them of the failure that occurred in your 830, using their 6146Ws. I also would ask them if the 6146Ws they sold you were manufactured in China. With all the failures of Chinese vacuum tubes these days, I stay away from any Chinese vacuum tube.

Topic: 46554 Message: 46557

Thanks, Wiz.
Being "unmoderated", does that mean I can mention I'm attempting to sell "Golden Hemostat" buggered up radios or do I have remaining probationary time on that front?
No idea what my join date was or when my 30 day probation ends....
Are there additional rules for that I should find and review?
Or would it be Ok for me to now post (only occasionaly, not to be burdensome with my pushing product) a link to my overpriced offerings on eBay?

Thanks Joe, I like it here.
Wonderful bunch of men you have collected here.
I feel refreshed from the feeling of exasperation I was feeling with my Millwright Union.
A years worth of work ($100,000) 5 miles from the house and they have let me have NONE OF IT.
Getting back into Amateur radio after 42 years was a good decision for me.
I've spent a crapload of money, not made a dime, but I'm happy.
I'm also happy that I'm slowly being accepted here. It's a good feeling.

Now if I could just get the "Breakfast Club" to pay more attention to my political views.....
Thanks to all of you.

"All it takes for evil to succeed is for good men to do nothing".

Tom- n8nma & Michael-kd0wsj

The benevolent, great and powerful Co-owner of OZ, has granted your request for "un-moderation."

At times the Wiz gets behind.

Thanks for joining and being a part of this great group. Remember, the policies still apply.

Happy Holidays

Topic: 46257 Message: 46558

I forgot the mention. Vacuum tubes people buy and let sit on the shelf for months/years on end can easily result in gas entering the vacuum from around the tube pins. This gas collection, if accumulated in high quantities, can result in an arc occurring which is what happened with the 6146A in my HW-101 that sat for 20 years.

Don't misunderstand me! I am not saying the 6146Ws RF Part sold you, sat around for years.

Quite often hams buy spare tubes. Many of them sit on the shelf for months and years. If you plan on purchasing spares you should use those spares on a periodic basis. The gas absorbing/eliminating element is the "Getter" element and it is attached to the "Plate" of the tube. Low power and receiving tubes all have it. The "shinny" chrome coating on the inside of the glass envelope is where the "Getter element" is located. You can see it. The element can be a round cup, a square, or wrong wire. The element is always attached to the PLATE. The plate gets hot when current flows in the tube. The heating of the plate causes the getter element to get hot which helps absorb gas in the tube. You will not find the getter element connected to any element in the tube except the plate!

Mike:

Very good observation. I quickly jumped to conclusion that they were NOS JAN Sylvania 6146W as that is only ones I have bought from RF Parts. I agree have never heard anything good about the actual newly manufactured ones from China. Never seen one in a rig yet. I would be very hesitant to try any, but would be curious to see how they hi-pot. Maybe they are struggling with quality control issues or dont understand the service they will be placed in.

Sure would be good if someone could remanufacture the Matsushita S2001A and RCA 6146B tubes to same quality level as the originals. Still find S2001A going strong in rigs to this day.

Terry K9TW

Greetings group,

I have obtained 6146B's & W's from "vacuumtubes.net" and "RF Parts." Have not had a problem with tubes from "vacuumtubes.net." RF parts honors their guarantee as I bought some "new" 6146B's" Well...they said "TAYLOR"....American name...good to go...no...made in China. Blew the cathode R's on my 830. I'll stick with known American made tubes...maybe a bit more $...but worth my time. Maybe I need to build a hi-pot, as I have bunches of final tubes sitting around...project for another time maybe.

Happy Holidays to all.....

>Very good observation. I quickly jumped to conclusion that they were NOS JAN Sylvania 6146W as that is only ones I have bought from RF Parts. I agree have never heard anything good about the actual newly manufactured ones from China. Never seen one in a rig yet. I would be very hesitant to try any, but would be curious to see how they hi-pot. Maybe they are struggling with quality control issues or dont understand the service they will be placed in.

I have made several purchases from RF Parts. Their tubes are NOS, American made unless otherwise specified. They sell stock from China, but they tell you when it's not American made.

Michael,

  you were approved for membership on 11-28-13. You may "advertise" your HAM RELATED items here at anytime, but not as a continual business venture. There are several member of this group that do from time to time, advertise their wares...that's ok. There's no set number of times but, if it gets to out of control...OZ could involved. If you choose to advertise, and then get interest in your item(s), please take further "conversations" regarding that/them off-list. By that I mean, direct contact between you and possible buyers.
Basic rules are listed in the "FILES" section of the home page of this group. Poke around there,
as there's lots of good info.

I'm glad you like it here and hope you can stay around for a while.

Terry,

This is an absolutely outstanding explanation of the bandswitch operation. I thank you for taking the time to post this. I need to read this again, more than twice, to make sure I get all the knowledge I can from it. The Kenwood hybrids are exceptional in my opinion, and they interest me very much. I completely refurbished my Hammarlund SP-600 and thought that was complicated. Well, the TS-530S is whole other kettle of fish.

I will post a comment again after studying your post. Thank you again! 73

Steffen (KA2KNX)

P.S. I didn't think you were giving me a hard time, but I do know the importance of being precise in responses. I generally don't like to post responses like, "...try this...ok, didn't work?...try that..., etc."

Thanks Joe,
November 28? been a month already? Or 7 weeks? Nah.....
Or am I the first to get aproved in 6 days?

My contact info is on QRZ.com if anyone wants to call and tell me
what a loon I am.
No, I mean if you want to comment on my speeling or my radio ad on eBay.
Yeah, like my wordage here, way too voluminous....I know, but that's me.

I started at $750 which I firmly feel was a fair price, with warranty!!
I wouldn't expect the guys here to be interested in it knowing my unconventional techniques for restoration/prevention. Also that most here know they can pick up a great rig at an estate sale or a Hamfest much cheaper and spruce them up themelves. Let's not forget I am quite ignorant of most of the Knwd design and it'll be awhile before I'm up to speed, don't tell them over at eBay!
Here:
http://www.ebay.com/itm/271351198316?ssPageName=STRK:MEWAX:IT&_trksid=p3984.m1423.l2649#ht_2935wt_888

Feel free to comment but please do so to my personal email addy.
I don't expect it to sell but that's OK, I'll keep it.
Until my TS-830S Gold Label is 100% I'm in no hurry to move it.

I'm just crazy enough to maybe give it to Joe Mcneil of the microeffectlive.com (Patriot radio) for raffle to help support the microeffect even though I'm broke, somebody has to do it. I'll probably do one of the 820S units, midrange quality cosmetically, refurbed with new tubes.
Makes better fiscal sense for me right now.
Dadgum service manual for 830S just showed today!! 3 Weeks....
Timing is everything, wood is stocked, burner going, most everything is done in the greenhouse except 2 hours finishing the woodburner out there.
Weather can be bad for days and I've got radios to work on and about $1000 in parts stockpiled and some extra boards relays tubes you name it, even parts radios.... Gonna be a long cold winter and I've got plenty to occupy my time indoors now. No more depression, my Union can Kiss my .
Corn, hay, wheatstraw all stocked for the critters in about 4 places today. About 12 turkeys and about 6-8 deer out back. Saw 2 big deer today. I think the big 10 point is still in my back yard.
Time to do some meat canning.

Had to take down my G5 and my fan 3 band dipole this afternoon. Bad ice storm here today, my turn I geuss, 1/2" so far. I'm not going to drop 'em to clear ice every 4 hours.
Parachute cord and pulleys, pretty slick.
Swedish dipole is the only one up, don't much care for that one and it's short so I don't think the ice will bring it down. Although I think that was the only one that would tune on 28 Mhz.

The 830s GL, man said it was "choppy" on the air. Sounds like he was saying it was overdriven? Said he was "tired of messing with it".
Any suggestions on where to start with it?
Common mods or?
Bought for $150 and $100 for a SM-220 monitor (stole 'em!!)
I may drag her out later tonight. To hooey with the 820S for now. Been waiting on that darn paper manual for 3 weeks.
Thanks Jim!! @Hybrid.

Yeah, I know alot of info "off topic" but you gotta admit,
I'm entertaining!!!

I wouldn't panic too much about old tubes letting in air.
Most of the problems occur during use when the the glass to metal seals
around the leads
heat and cool.
I have a "bright emitter" triode made in 1923 that still works fine.
Admittedly a low power tube (but with a 5 volt 1 amp heater). Technology
has come along way since then.
The biggest problem with shelf life is in tubes like "magic eye" tuning
indicators. They have a lot of metal and phosphors inside that slowly
"outgas" and as a result do get "soft". That's why they fetch a premium
among vintage radio enthusiasts and also why I designed some solid state
replacements that even look the part as they are getting so rare.

United States Patent 3742261
Teledyne, Inc. already owns this one.

Now, whether or not they have any specific tube replaced with one of
their modules, that I cannot tell. But I suspect that if they do have
solid-state 6JE6's, the price will be huge.

Hello all. My 830s receiver comes up in volume at every static crash or even a TX tap on the morse key. Then slowly drops down again after a few seconds. Even into a dummy load. Also notice that the RX is more sensitive when the RF control is set at about 8 rather than 10 (max).

Any ideas please ?

Topic: 46257 Message: 46575

No such luck Mike! After 60 years of Ham radio and electronic
engineering I still remain unconvinced about solid state transmitter
finals. Most solid state Linears are actually slightly LESS efficient
than tubes. Typically 50% versus 67 % for a well designed tube linear.
They also tend to be rather delicate in terms of matching.

A solid state "magic eye" can be made to work well using the voltages
and signals available
in a tube radio without major surgery. I just finished one today. Making
a 150 watt solid state amp to run of 900 volts would be quite a feat!!!

Still fighting with open cathode resistors in the 6146 final in my TS830S I am facing a new problem. The RL1 relay in the AF unit clicks on for 2 or 3 seconds when I power up the RX, and when I change modes between LSB, USB and CW. I havde gently poked the relay when it is stuck, but with no success. Time to order an RL1 replacement from K4EAA?

Topic: 46576 Message: 46579

Peter: OK can happen to any of us.

One more thing for you to consider. Normally I do not recommend modifying KW hybrids. The one exception I finally caved in on was driven by multiple cathode resistor blowing and the needless stress on the HV filter caps, rectifiers, power transformer, and banging the indicator violently against the peg or burning out the moving coil. I experienced repeated arc over events with my own hybrids using hamfest pulls, hamfest NOS tubes, and RF Parts and other sellers NOS tubes. Didnt matter if Jan 6146W or RCA or GE brands.

Also, repeatedly having to remove covers and unsolder and resolder with risk of lifting foils not to mention the down time led me to modify all my hybrids and many of my customers rigs so we no longer have cathode meter shunts blowing open.

If you install a series string of 3 silicon rectifier diodes across the cathode meter shunt resistors you will limit the IR drop to approx 2vdc and should never experience a blown resistor again. With an Anode to Cathode arc over it is possible that you could pop a diode (I have never experienced it), but far easier to replace a diode than a cathode resistor.

I used 1000 PIV 2.5A diodes that I had in junk box but any will work. Place 3 in series with the anode end of string tack soldered to Pin 1 tube socket lug and connect the cathode end of the string to chassis ground. I do that by installing a small solder lug at a Final board hold down screw.

You can see a picture of the mod at WB4HFN website under the Articles and Info tab.

If you want to look at DC hi-pots or BVTs take a look at K8CU. Mine is clone of his using microwave oven HV parts. I have adjustable range from 0 to 5kv vdc and current limited to approx 100ua. I made it to test 6146 tubes. Need higher voltage if you want to test 572b or 3-500Z etc.

Only way I know to test 6146 finals NOS or otherwise is to hi-pot test them. I use to test run in old Heathkit DX 60 transmitter and that just didnt duplicate KW hybrid conditions. Good ones will hold off 2000 to 2500vdc with 10 to 15ua leakage. Some will arc over at 1000vdc and then test good on the 2nd go and others will not.

I also realize you cant "getter" a 6146, but I am a believer in rotating spares perhaps on annual basis when you do your pm such as fan lube. I think Mike W5RKL mentions that he also rotates his spares. He has a lot of tube experience. Leaving them on the shelf for many years thinking you will have a viable spare when you need them has not worked well for me.

http://www.realhamradio.com/High_Voltage_Breakdown_Tester.htm

I dont expect you to blindly do as I say. Do your homework and make sure it makes sense to you.

Assuming you are not losing your operating bias voltage my bet is you are experiencing anode to cathode arc over.

Thanks for that Terry. I've been wanting to ask for info on that tester.
I had no clue what you guys were taking about with abbreviations and assumng everybody was on same page, I'm still waiting on the book....
Sounds like a handy piece of test equip and
I think I have all those components....even the plexiglass.

Another set of used 6146 I thought were good turned out to be junk.
That makes 6 out of 7 sets in 2 weeks.
Getting old (yeah me AND the tube issues).
I'm going to follow the lead of buying only from RF parts and the other suppliers here mentioned.
In future if all you men would mention what you've paid for tubes it would help me. I know I can go look, but like all the abbreviations used here, it's lack of complete information that I struggle with.
The one good set I've purchased came from bobsezshop on eBay.
$62 + $10 for shipping for "NOS" tubes with driver.
With all the wasted time ordering, testing, contacting deceptive sellers with ndon't own tube checkers (but sound like they do), repacking, reshipping, waiting for my money back.....
I have a hunch I'd be time and money ahead to buy only from reputable tube suppliers with no-hassle return policy and good reputation,
irregardless of price.

New problem with the radio I have for sale, I've been running it while waiting for tubes for others and for some dipstick to fix these other radios.....
Ice storm yesterday, cleared ice off 3 dipoles at 2pm, 1/4" thick then. Lowered by parachute cord through pulleys up trees. At 6pm dropped them again, rolled up my G5 and My 3 band fan, another 1/4" of ice, 1/2" on every thing now. I left up my Swedish dipole, it's short so I figured it would hold up .Tunes good on 21 and 28 Mhz but not so well on lower freqs I'm usually on.
Tuning up at 9pm on 80 Mtrs it goes up to 125 watts????
At 11pm on a diff 80M freq I tune again, it goes beyond 125 to 150 and swings over 200....., I went out at 11 pm in the rain with headlamp and .44 and put my G5 back up.
Damage is done, nothing over 15 watts out of the damaged tubes now even with my G5.
Is that "thermal runaway" or what? Fried tubes for sure, they now test as junk.
I was running my last 2 good tubes from 2 weeks ago. One Khainese and a GE both testing about 80%. They've performed well, twice last week people asked "what linear are you running"?
Now with known good tubes I'm not getting above 15 watts. I've replaced the doorknob cap and the .01 2KV and the 6.8uh with "Final Cage Repair Kit" from Jim at Hybrid Restore.
No change, still at 15 watts.
I'm about to replace the 4-20 ohm Cathode resistors, the 2-100 ohm Grid resistors and the 470 on the rectifier board, 530/830 resistor kit.
The cathode resistors in circuit show 5.1 ohms in circuit.
Board is out, about to get after that.

Am I doing the right thing or am I going in the wrong direction (again!!) since I'm not really seeing any damage?
I don't have an LCR meter to test the old output cap I replaced with new doorknob, but I recall low output is often that component.
does Terry or anybody have the time or inclination to give me todays lesson?

On my Gold Label TS-830S (tried it this morning also....), I geuss I did put some work into it 4 weeks ago, have a 14 item list, before I decided I needed a service manual. Yes I know pdf is online, I have I think most of them now, I prefer paper.
(I like to color the lines....)
I need some guidance. Yup, yer right I need more than that...
Wonder if Ken needs somebody to sweep the floors....
Michael///KD0WSJ

Subject: RE: SV: [TS-520_820_530_830] RE: TS830S RL1 relay

Peter: OK can happen to any of us.

One more thing for you to consider. Normally I do not recommend modifying KW hybrids. The one exception I finally caved in on was driven by multiple cathode resistor blowing and the needless stress on the HV filter caps, rectifiers, power transformer, and banging the indicator violently against the peg or burning out the moving coil. I experienced repeated arc over events with my own hybrids using hamfest pulls, hamfest NOS tubes, and RF Parts and other sellers NOS tubes. Didnt matter if Jan 6146W or RCA or GE brands.

Also, repeatedly having to remove covers and unsolder and resolder with risk of lifting foils not to mention the down time led me to modify all my hybrids and many of my customers rigs so we no longer have cathode meter shunts blowing open.

If you install a series string of 3 silicon rectifier diodes across the cathode meter shunt resistors you will limit the IR drop to approx 2vdc and should never experience a blown resistor again. With an Anode to Cathode arc over it is possible that you could pop a diode (I have never experienced it), but far easier to replace a diode than a cathode resistor.

I used 1000 PIV 2.5A diodes that I had in junk box but any will work. Place 3 in series with the anode end of string tack soldered to Pin 1 tube socket lug and connect the cathode end of the string to chassis ground. I do that by installing a small solder lug at a Final board hold down screw.

You can see a picture of the mod at WB4HFN website under the Articles and Info tab.

If you want to look at DC hi-pots or BVTs take a look at K8CU. Mine is clone of his using microwave oven HV parts. I have adjustable range from 0 to 5kv vdc and current limited to approx 100ua. I made it to test 6146 tubes. Need higher voltage if you want to test 572b or 3-500Z etc.

Only way I know to test 6146 finals NOS or otherwise is to hi-pot test them. I use to test run in old Heathkit DX 60 transmitter and that just didnt duplicate KW hybrid conditions. Good ones will hold off 2000 to 2500vdc with 10 to 15ua leakage. Some will arc over at

1000vdc and then test good on the 2nd go and others will not.

I also realize you cant "getter" a 6146, but I am a believer in rotating spares perhaps on annual basis when you do your pm such as fan lube. I think Mike W5RKL mentions that he also rotates his spares. He has a lot of tube experience. Leaving them on the shelf for many years thinking you will have a viable spare when you need them has not worked well for me.

http://www.realhamradio.com/High_Voltage_Breakdown_Tester.htm

I dont expect you to blindly do as I say. Do your homework and make sure it makes sense to you.

Assuming you are not losing your operating bias voltage my bet is you are experiencing anode to cathode arc over.

Dick,

I was waiting for you to recommend this mod. I've installed it on I think 2 problematic hybrids and I've never had a problem since doing this. I know several other on the Kenwood net that have also made this with good results. Great modification.

http://wb4hfn.com/KENWOOD/Articles/Technical_EX-004.pdf

Have any others we can write up?

Mark, WB2KNR

You have to be very careful with a dc hi-pot of any kind whether home brew or a commercial unit like Associated Research or Hipotronics brand. Even if current limited to ua range they can give a nasty shock or worse. So before embarking on this do your homework. Some folks use a negative ion generator or a power supply from a copy machine as the basis for one.

I am not sure what you mean by 9 pm and 11 pm? I assume you are talking about the position of the Plate Load capacitor? We dont load to a position on the Plate Load cap. That position varies depending on what impedance your antenna presents to your radio and how much load you want to pick up ie plate current. The ,more you open the plates the less the capacitance the greater the Xc. Since the Plate load cap is in parallel with the load as you increase the Xc less tank circ current flows thru the cap and more tank circ current is transferred to the load impedance. Some people like to make cheat sheets of Plate Tune and Plate Load cap positions and that is fine to get you in the ball park and for quick QSY as long as impedance presented by antenna doesnt change. If more than one antenna then need multiple cheat sheets.

Best way to load a Class AB1 ssb linear amp is to load to maximum rf output either on an external wattmeter or by using the RF meter relative power position on the rig just as KW directs you to do. We do that without exceeding the plate dissipation of the tubes. For a TS-830 that is max of 265 ma. However most owners load conservatively to no more than 225ma. If you load to approx 100 watts output into a 50 ohm load you should see no more than 200ma to 225 ma of plate current. A well aligned spec TS-830 should load to 100 watts into 50 ohm dummy load at close to 200 ma on all bands. Remember the radio is rated at 180 watts dc input.

The loading instructions in the TS-830 operating manual is very clear on how to use the RF meter position to load to maximum relative output power without exceeding max Ip. They do this as the old dip and load method is not a good way to load a Class AB1 transmitter because when the transmitter gets nearer to being fully loaded the dip becomes very shallow while the output power peak displayed on the RF meter position or an external wattmeter is not shallow. The peak power displayed is very obvious and well defined. In the case of the RF meter position it is peak Rf voltage at the SO-239.

I have never seen an un-modiifed TS-830 that could produce more than 125 to 130 watts output max. It is not possible to load to 150 watts to 200 watts output. The power supply will fall flat trying to do that. If you saw 150 watts to 200 watts on your wattmeter you needed to switch to reflected power. My guess is it would have been quite high.

Lastly why change out cathode resistors that measure 5.1 ohms?

Topic: 46585 Message: 46585

Hello group, my name is Linas , im 17 years old and this is my first transceiver. Its my first time writing here and i hope i can explain what im trying to do and what i found out.

Its really hard for me to tell you all so i also made a video showing all the "stages" of it breaking down. http://youtu.be/ovTtbdvWej4

At first i suspected a loose wire or a bad solder joint somewhere around the digital display unit, because touching the connector cable that
goes to the freq display made alot of noises and made the frequency or audio jump around. I inspected both cables that go to the display unit and they seem fine, so do the solder connections.

As you can see in the video now most of the
time the audio becomes dull, display is jumping around and tx isint working at all. Tapping the side or the top lightly tends to help sometimes, even when i got the rig half a year ago or so sometimes it would need a light tap in order to stay in
place after turning on.
I am really desperate here and looking for ideas.

Thanks,
Linas LY5AT

Is it normal for my VFO-230 to lose its stored settings after being unplugged? Page 47 of the service manual states that the power is interlocked with the main unit. It also mentions memory stays live when the main is switched off when using AC power. It doesn't specifically mention memory loss when unplugged from AC power.
Thanks,
Ralph KB1ZYI

when I was changing out the hv caps a small black wire came undone.

there is a ground pin between the hv caps with 3 black wires
1. heavy gauge black connects to neg terminal on hv cap
2. small black wire goes through groove in top of metal wall .it is part of a group of wires
3. this is the problem. 4 to 5 inch black thin wire. I believe it should go through a square cutout into the transformer section. what does this connect to?

i am guessing the neg terminal on the big transformer?

can one of you guys take a look at your 520se and let me know

46590. Kenwood Net Update (December 22, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-22 21:49:13 UTC
From: Mark Gilger
Topic: 46590 Message: 46590

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in
existence on November 1st, 2013. The yearly
check-in totals are posted at the bottom of this
message. It showed we had a 10% increase in our
Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

The Saturday net on 40 meters had 20 check ins
under good band condition. There were 3 new check
ins, KD8VTO, KD6TWC, and N8WZP/AE. We had the
following number of radios checking in.

4 running TS-520(x)
2 running TS-530(x)
4 running TS-820(x)
4 running TS-830S

I was using my TS-830s.

The Sunday□s 20 meter net had 21 stations
checking in under good band conditions. There
were 3 new stations checking in, KA1LQE, N5DHB, and W7JJH

Out of those, there was:

2 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
4 running TS-830S

I was running my 820 twins, TS-820s + R-820.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.

Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 65, Sunday☐s total = 71 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHo
mePage.htm

73's,

Ron,

I do believe that this wire should be connected to the "GND" post on the HV unit. Also, no disrespect intended but, this is an example of why you should take notes, draw a diagram or,
take some pictures before you start to do anything that involves removal of wires/connectors.
It just makes life a bit easier

Hello there.
Well - the meter reacts OK to loud sigs on RX. Both in AGC Fast & Slow.
Here at the moment on 14.050MHz with background noise showing S1+ on the meter (band rather dead now).
A short DIT of CW TX then gives a slight increase of RX volume, but no change in S1+ receive meter reading.
After about 5 seconds the RX level is back down to original levels.
This happens even with AGC off.
Just curious to know if this is normal or if there is a minor fault somewhere.

Not tried on SSB - CW only here.

OK Mark: I wasnt sure.

Well as you know not a big fan of modifying these rigs. Only did the protection mods after final tube arc overs two or three times in about a weeks time. That got pretty old.

I am OK with the "huff and puff" boards you installed in your rigs.

Some mods are pretty benign like changing out the product detector and balanced modulator ring diodes to Schottky diodes. I have seen a few rigs where instead of buying the remote VFO the range of the RIT has been extended to around 5k. These mods are really no big deal and you dont butcher the rig.

I have thought about screen grid regulation either with zener string or mosfet shunt regulator but probably wont do it.

Speaking of Dick might ask him to take some good close up photos of his wire jumper repair of the bandswitch decks and post on Rons website?

I thought of you at Fort Wayne. Most likely my last year as it was really small this year. Another ebay casualty.

Have a great Xmas.

The memory is volatile.

Power stays on to the VFO-230 so long as it is provided with AC power. The interlock just brings the VFO out of “standby” when you turn on the radio.

Subject: [TS-520_820_530_830] VFO-230 loses memory and freq settings when unplugged.

Is it normal for my VFO-230 to lose its stored settings after being unplugged? Page 47 of the service manual states that the power is interlocked with the main unit. It also mentions memory stays live when the main is switched off when using AC power. It doesn't specifically mention memory loss when unplugged from AC power.
Thanks,

Only installed the "huff & puff" (VFO Stabilizer) on the TS-820 and R-820. The other radios don't need it, so will stay original.

I'll ask dick for some pictures and see what that's all about. Seems he is getting real proficient at removing the wafer boards from the RF board and repairing them. Bought a nice de soldering tool to assist in that work.

It's too bad about Ft. Wayne. From the old days to now it's probably down sized maybe 3/4. Really used to like going there. Still have Dayton to look forward to.

Ralph,

From my experience, I have 3 of these units, once you have removed the primary 240\120v power supply regardless if it is connected to the radio or not, you will loose all your memories stored in the VFO. The other problem that most people encounter is, if left unplugged for extended periods and then reconnected to power\radio the ext VFO works well for a very short time then the encoder becomes erratic to the point of not working at all. The simple fix without any technical requirements is to connect to radio and power for 24 hours and it will come back to return to perfect working order. I leave all mine connected to 240v. Whilst I haven't gone probing I would suggest that the caps are a bit suspicious.

Regards,

Dave

First I wish I had S1 background noise! Hardly ever see that at my QTH.

OK this short TX dit.... Is it with heaters on and rig loaded and actually producing RF output in CW mode? Do you flip to Send and then back to Rec after sending the dit or are you using VOX to send the dit? Do you hear the side tone oscillator?

As I understand it you see no change in S-meter only a noticeable change in the back ground noise to a higher audio output level in the speaker and it stays high and decays back down to where it was before sending the dit in about 5 seconds.

Is this correct?

If so, I have to say never noticed it and I have two TS-830s. Will look at schematic and see if something jumps out at me. Even though you say not seeing any change in S-meter indication I would want to monitor the AGC bus (rail) voltage as a first step to make sure it is not rising slightly. If anything with the TX dit you might expect it to drop slightly as RF-1 is derived from the 9vdc series pass regulator on the audio board. RF-1 should be set to 3.6vdc and is applied to the AGC bus thru the RF gain pot wiper RFG and thru a 2.2 meg resistor to the bus.

If AGC bus voltage is not moving then almost has to be on the audio board. In CW mode there is some diode switching that takes place to switch in the CW audio filter to tailor the audio response for CW reception. This is done by routing the product detector signal thru Q2 and a low pass filter in its output. Lots of caps in this circuit and maybe something changed in these RC time constants? Just guessing at this point.

Well I have to say in about 50 years first time anyone ever related a transmitter loading problem to me and included the time of day!

Where is your resting plate current set at?

If you are able to peak the ALC indication in TUNE mode and make the initial plate current dip in Tune mode with the CAR Level Pot (There is no IP pot so I assume you are talking about the CAR level pot?) in full CCW position then sounds like you have a open ring diode on the Balanced Modulator. Otherwise dont understand how the CAR Level Pot is at full CCW when you are moving on to loading the rig in CW mode. Should be where you left it after making that initial plate current dip.

Topic: 46576 Message: 46606

Are you saying that after peaking ALC in Tune mode you then change meter from ALC to IP position and flip to Send and the meter pegs? OR

Are you saying you can dip the plate current in Tune Mode and then when you place mode switch in CW mode and try to check the plate current dip again this is when the meter pegs?

It sounds to me like you have a problem with the bias voltage adjust pot.

I would pull the finals and measure the operating bias thru its range to make sure it is there and smooth from full ccw to full cw of the pot. Have to be very careful working in the PA cage and make sure that the dangling anode caps wont go to ground as you will have 900vdc on them during this test.

I recommend using an analog VTVM to monitor the bias voltage at control grids of the finals as opposed to a DMM. Measure directly on Pin 5 at the 6146 socket lugs on the final board. Report back the voltage range that you get. Will be approx -100 to -30. Return it to -60 after testing.

Regarding plate current dip:

In Tune mode with the Plate Load capacitor plates fully meshed (full CCW) you should see a max of approx 100ma with the Plate Tune capacitor off resonance and should get a dip down to around 50ma at a peak of approx 15 watts output on your wattmeter. If you have the Plate Load capacitor plates open then of course will see less of a dip. Suggest to all new folks to fully close the Plate load cap until they get proficient at loading.

Michael,

You said the "HV" is "450VDC" with the "SG" switch set to OFF????

You then said the HV is "750 volts" with the "SG" switch OFF???

None of that makes any sense.

The "SG" switch has nothing to do with the HV meter indication. If the meter switch is set to "HV" with the transmitter keyed and the meter indicates "450VDC" on the HV scale, then one of the HV filter capacitors has failed. The HV supply in "ALL" KW hybrids is a "voltage doubling" supply. Are you sure you are looking at the HV "RED" scale?

Also, you said with the "SG" switch "OFF" you get "50 watts output". That is not possible! If the SG switch is set to "OFF" then the final amplifier will have zero RF output. You will be able to achieve an ALC peak adjustment in TUNE mode but you will not see any IP current with the transmitter keyed. Do you know what happens when the SG switch is set to "OFF" and what happens in the final tubes with the SG switch in the "OFF" Position? If you do not understand what the SG does and how it affects the final amplifier then I suggest you watch my SG switch videos:

www.n6wk.com/w5rkl/SG Switch/

Neutralizing the final occurs on 10 meters.

Many thanks for the detailed info Terry.
It is just a minor niggle and thank you for all your help.

The short TX is indeed with 100w to ant. I do not use the SEND, I use VOX switched on with minimum gain.
Sidetone audible.
What is interesting is that the same slight increase in receive occurs when a static crack is received.
It is only a minor thing and I can live with it :0)

(Background noise can vary a lot here in the middle of town - sometimes S9 !)

Is this correct?

If so, I have to say never noticed it and I have two TS-830s. Will look at schematic and see if something jumps out at me. Even though you say not seeing any change in S-meter indication I would want to monitor the AGC bus (rail) voltage as a first step to make sure it is not rising slightly. If anything with the TX dit you might expect it to drop slightly as RF-1 is derived from the 9vdc series pass regulator on the audio board. RF-1 should be set to 3.6vdc and is applied to the AGC bus thru the RF gain pot wiper RFG and thru a 2.2 meg resistor to the bus.

If AGC bus voltage is not moving then almost has to be on the audio board. In CW mode there is some diode switching that takes place to switch in the CW audio filter to tailor the audio response for CW reception. This is done by routing the product detector signal thru Q2 and a low pass filter in its output. Lots of caps in this circuit and maybe something changed in these RC time constants? Just guessing at this point.

OK John
I will think on this and if come up with anything else will let you know.

As you know the idea of AGC is so you do not have to ride the RF gain pot to prevent strong signals from blowing your ears off. If strong static crashes are causing increase in AF level then perhaps there is an AGC time constant issue. Large value caps at feed end of this bus and smaller values at IF and RF gain controlled stages.

You can measure the bus impedance if you unplug Conn 8 on IF board so you dont read back thru the RF gain pot. Connect ohmmeter to Conn 15 Pin 3 AGC and should see a minimum of approx 4.5 meg ohm. If much lower than this then you have leaky cap or caps which will effect AGC time constants.

You can play around and temporarily hang different values of caps on the AGC bus to observe the effect. Can easily connect at Conn 15 Pin 3 on the IF board. Start with something like a .22uf.

Also as you know many different ways to run. Some Ops use the RF attenuator, Some run with AGC off and do use the RF gain pot.

Have a great Holiday season.

Michael:

I really want to suggest that you sell off couple of these Ebay junkers and buy a Heath DX35 or DX40 or DX60 and have fun refurbishing it and learning how to load a Class C CW transmitter.

When done you will have a piece of test gear that will allow you to test all these 6146 and S2001A tubes you have one at a time under dynamic RF drive conditions before you install them in a KW hybrid.

Wont be same DC conditions, but should screen out most "bad" tubes from good ones.

Lastly I always have a problem trying to teach new people for several reasons:

1. I forget they lack knowledge and experience at a fundamental level that is just 2nd nature to me after all these years. Hard for me not to use the parlance and sometimes speak as we did a long time ago.

2. Trouble shooting is a systematic and logical way of thinking. Cant flit around like a fart in a skillet. Takes some fundamental electronics knowledge, RF radio communications knowledge, modest amount of test gear, how to use it, and lastly KW hybrid specific experience (where are the test points, how to perform service manual steps, how basic circuits work etc).

3. I cant see your face and eyes so have no idea if the head lites are on or not when I make a statement of ask a question.

4. I refuse to just give an answer as some would prefer. I try to include some of the underlying fundamentals. Absent that there can be no learning.

5. I tend to waste a lot of time and keystrokes with responses that turn out to be based on mis-information.

All pretty much short comings as a teacher on my part. Maybe someday we will be able to show and witness instead of just tell.

So at this point I think best if the other members jump in here and help you . I have a back log of bench work and should not be hanging out here until that has been caught up.

Responding in this medium takes a lot of time which I cant commit to at this time.

Best holiday wishes

Well I have to say in about 50 years first time anyone ever related a transmitter loading problem to me and included the time of day!

Where is your resting plate current set at?

If you are able to peak the ALC indication in TUNE mode and make the initial plate current dip in Tune mode with the CAR Level Pot (There is no IP pot so I assume you are talking about the CAR level pot?) in full CCW position then sounds like you have a open ring diode on the Balanced Modulator. Otherwise dont understand how the CAR Level Pot is at full CCW when you are moving on to loading the rig in CW mode. Should be where you left it after making that initial plate current dip.

With the KW hybrid HV fliter caps (as with all electrolytics) there are premature catastrophic failures and life span failures.

These are 35 to 40 year old rigs and common to find that the 900vdc HV filter caps have swollen rupture vents, white crystalline powdery deposits at the vents, and almost always elevated ESR. Often with the capacitance value measuring on a digital LC bridge within +/- tolerance.

Many factors contribute to the normal "bath tube failure curve". Life span is affected by operating temperature, charge and discharge cycles, inrush current, ripple and RF, and the electrolyte evaporating over time among other factors. They can and do simple just wear out.

I am not a big proponent of total recap as others are and do not subscribe to the claim that electrolytic cap leakage is the major contributor to Hybrid operational issues. I simply have not experienced that and do not recap as a pre-req for repair and alignment or as normal preventive maintenance tasks.

However, the exception I do make is with the HV filter caps. I recommend replacement of the HV filter caps under preventive maintenance umbrella based on the high energy fault contribution and needless stress on the power supply and possible collateral damage that catastrophic capacitor failure can cause. Just the tarry mess sprayed around is to be avoided in my opinion.

Of course just one mans opinion. .

Terry K9TW .

If I may add a comment to Terry's response.

If one of the HV caps has failed, the pressure vent has ruptured,
replace both capacitors. Replacement HV capacitors may be purchased from
Ken, K4EAA, see his website at k4eaa.com for details and availability of
the HV replacement capacitors.

Nor am I! I've scrapped too many nice old bits of equipment because people have gone "HERP DERP IT NO WORK MUST BE CAPS LETS RECAP IT" and introduced all manner of faults - all without ever fixing the original fault.

In 20-odd years of repairing stuff, I've changed maybe a half a dozen electrolytics that weren't in cheap crappy switched mode power supplies (and more Amstrad SRD1000s than I care to remember - cheap crappy SMPSU, left to bake on top of the video recorder with the vents blocked by a copy of the Radio Times). Lots and lots of disc ceramics, though. They *do* fail and go leaky. About the only time I've seen electrolytics genuinely fail is when the rectifier preceding them has gone shorted and it all gets noisy.

Never use a pair of 450VDC capacitors to replace the KW hybrid HV filter capacitors! The resulting working voltage will be too low, 900VDC.

The working voltage of each series connected capacitor, "adds" but the capacitance divides, the "opposite" of resistors in series! Therefore, with two 120ufd 500VDC capacitors connected in series, the total capacitance is 60ufd (120 x 120 / 120 + 120 = 60) and the working voltage is 1000VDC (500 + 500 = 1000).

If the KW hybrid HV filter capacitors are replaced with two 120ufd 450VDC capacitors, the total capacitance would still be 60ufd BUT the working voltage would only be "900VDC" (450 + 450 = 900) which is too low for the KW hybrid's HV supply's no load output voltage!

Filter capacitors that are connected in series, should be the same capacitance value and the same working voltage rating. The working voltage of each capacitor should, when added together, exceed the "no load" output voltage of the power supply. When connecting capacitors in series, it is highly discouraged to mix capacitors of different capacitance values, even if the voltage rating of each capacitor is the same. When capacitors are connected in series and AC voltage is applied to the capacitors, the AC voltage pays no minds to the capacitor's high internal resistance but rather divides the AC voltage inversely proportional to the capacitors
capacitance values even with equalizing resistors connected across each capacitor. That means you should not connect an 80ufd capacitor in series with a 150ufd capacitor even if both capacitors have the same voltage rating.

Equalizing resistors connected across each series connected capacitor, each resistor has the same resistance and wattage rating. The resistors act to equalize the voltage across each capacitor plus serve as bleeder resistors to bleed the capacitors to zero when voltage is removed. Each series capacitors charges "individually" throughout the AC sine wave cycle but discharge as a "single" capacitor.

Mike,
If you use a 105 deg C caps,450V caps is OK. They have much more headroom compared to the 85 deg C caps. It is real hard to find 500V caps these days and I will select 105 deg C 450V caps over unknown quality 85 deg C 500V caps anytime.
I have used thousands of caps for marginal head room and 105 deg C caps did not fail on the similar cases.

Hi Michael,

How about if you take a clear picture of the HV board so we could see what’s happening ? (assuming you have a digital camera or similar)

73 and all the best for the season to everyone 8-)

Rob VK3BRS

Subject: Re: [TS-520_820_530_830] TS-830 power supply

Well, wonderful. Blew a fuse.

HV caps replaced. I did a neat job of it. Soldering and wiring I'm real good at, it's one of those mechanical things that comes natural to me.

I need to know if I have the polarity on the caps right.

If so I've got another problem.

Before I spend an hour pulling the caps and rewiring again I'll wait for conformation if I'm right or wrong....

I think I got it Bass ackwards and that's why I blew a fuse.

Could I get a reply from somebody that is familiar with

Ken/K4EAA's HV kit HV 150B?

(see post below that I'm replying to)

I geuss the "Breakfast Club" gets another day of boredom without my irritations, dangit!

Merry Christmas!

Subject: Re: [TS-520_820_530_830] TS-830 power supply

I'm replacing the HV caps in my TS-530S that quit during the ice storm with my crap Swedish Dipole.

I have one set of caps from Ken, K4EAA, "HV repair kit" HV 150B, Nichicon 150uf at 500V, 105*C.

The new caps are marked for polarity but it is ambiguous to me.

Short caps with a grey strip up the side that has 0 0 0 0 0.

I see the base of the contacts also has a checkerboard pattern, almost like a +++++.

40 years ago the only thing marked on electrolytics was the + side.

I'm going to assume this IS the + side with grey strip and 0 0 0 with post stamped with checkerboard ++++.

Is that correct? Stripe is still + side?

Old tall caps are marked with black dot on Neg side, Nothing else.

Hopefuly somebody replies quick OR I have it right, or both!

Going through "NO Radio" withddrawal.

Pretty bad, 8 radios and none working 100%

I'm sure the armchair pilots of the "Breakfast Club" are missing my daily political rants that always piss them off!

Hey, I got some sleep! 3 hours!

Tried to go through tuning to review what I remember and correct my buggered up statements from yesterday.....radio has no IP at first tune steps....

No harm done replacing caps. No signs of other damage, It's quick enough. It's also the only fix suggestion I got yesterday.

(Other than learning what I'm doing and watching my wording more closely,

Sg off, sg off...!!! hi...hi.)

Side note to Terry, I had a Heathkit DX-40 when I was 13 and a Novice, 42 years ago. Miss it. Also had a monster National 5TA1 receiver with pull out coil sets, total of 4.

I wish I had not made that sad drive to the dump with them 15 years ago. It still bothers me. Good old freinds that I let down....

"Merry Flippin Christmas"!! Enjoy your families.

Subject: Re: [TS-520_820_530_830] TS-830 power supply

Never use a pair of 450VDC capacitors to replace the KW hybrid HV filter capacitors! The resulting working voltage will be too low, 900VDC.

The working voltage of each series connected capacitor, "adds" but the capacitance divides, the "opposite" of resistors in series! Therefore, with two 120ufd 500VDC capacitors connected in series, the total capacitance is 60ufd (120 x 120 / 120 + 120 = 60) and the working voltage is 1000VDC (500 + 500 = 1000).

If the KW hybrid HV filter capacitors are replaced with two 120ufd 450VDC capacitors, the total capacitance would still be 60ufd BUT the working voltage would only be "900VDC" (450 + 450 = 900) which is too low for the KW hybrid's HV supply's no load output voltage!

Filter capacitors that are connected in series, should be the same capacitance value and the same working voltage rating. The working voltage of each capacitor should, when added together, exceed the "no load" output voltage of the power supply. When connecting capacitors in series, it is highly discouraged to mix capacitors of different capacitance values, even if the voltage rating of each capacitor is the same. When capacitors are connected in series and AC voltage is applied to the capacitors, the AC voltage pays no minds to the capacitor's high internal resistance but rather divides the AC voltage inversely proportional to the capacitors
capacitance values even with equalizing resistors connected across each capacitor. That means you should not connect an 80ufd capacitor in series with a 150ufd capacitor even if both capacitors have the same voltage rating.

Equalizing resistors connected across each series connected capacitor, each resistor has the same resistance and wattage rating. The resistors act to equalize the voltage across each capacitor plus serve as bleeder resistors to bleed the capacitors to zero when voltage is removed. Each series capacitors charges "individually" throughout the AC sine wave cycle but discharge as a "single" capacitor.

The HV caps being sold by Ken, K4EAA, do not have "zeros" down the side. Those are "minus signs" pointing down the side of the capacitor to the "negative lead".

If an electrolytic capacitor is incorrectly connected in a power supply, i.e., negative terminal is connected to the Positive output and positive to the Negative connection then power is applied to the cap, the cap will be permanently damaged. That is why it is very important to install a replacement electrolytic capacitors "correctly" by paying attention to the capacitor's markings and the circuit the capacitor is being installed in. If this occurs a new capacitor should be used.

It doesn't matter whether the capacitor is rated for 85 degrees or 105 degrees, it's the working voltage rating that is important. Also, it is very poor and "unsafe" troubleshooting/repair practice to use capacitors in a power supply or circuit that have a working voltage that is equal to the power supply's output voltage or circuit voltage. You should always have a safety "working voltage" margin in any capacitor used in a power supply or circuit.

I dont brag about being good at anything. Very risky having a high opinion of ones self. OK to like yourself. Never good to be confident to the point of arrogance.

There is no way to really ever grade yourself in any endeavor. You are only as good as your competition and they are always raising the bar. Lots of competition on this site. Luckily most are willing to share. Just cant teach common sense, humility, touch, feel or aptitude.

The OOOOO symbols are not zeros they are meant to be oblong negative signs on the grey band on side of can. This is the negative terminal.

The stamped pattern on the terminal post is not Plus Plus Plus. It is a cross hatch pattern and is the negative post. That post is aligned with the grey band on the cap vinyl cover.

Agree it can be confusing. Some cans have the Positive terminal stamped with a + and some have the Negative terminal painted with a black dot. Best to consult the data and app note sheets when not sure or come here and ask.

Cannot reverse polarity them. Similar to a diode they have cathode and anode foils and most mfg. recommend no more than 1 to 2 vdc reverse polarity at room temperature. Look at the pressure reliefs cut in top of each can and see if it is now convex. Should be flat. If not convex, you could measure capacitance and ESR them and try using them again.

I might try that for my radio but I would not put back in a customers radio.

Michael,

As I stated before, the SG switch has nothing to do with the HV power supply output voltage.

The SG switch is set to the "OFF" position when neutralizing the final amplifier. You should not attempt to neutralize the final amplifier until you fix the HV power supply and the source that is causing the fuse to blow.

I recommended you replace both HV filter capacitors even if only one failed. Did you do that?

Also if you connected the replacement HV filter capacitor "backwards" then you should throw that capacitor away and install new fresh caps, connected correctly.

Michael,

I recommend you do not reuse that capacitor you installed backwards. Did you replace both HV filter capacitors or only one? I could be wrong but it appears you replaced only one HV filter capacitor. Do you understand the HV power supply filter capacitors are connected in "series" and that the HV power supply is a "voltage doubling" supply?

If I may make a suggestion, you need to slow down. You are asking questions but not waiting for answers before you proceed. If you have asked a question about a subject/topic or something you do not understand, you should wait for the answer before you proceed. If you still are unsure or do not understand, ask additional questions. Never make assumptions on anything, or "I think it's right...". You should always check/verify BEFORE you proceed. Making assumptions or following the "I think it's right.." concept of thinking can easily result in you being wrong which could easily results in additional problems you did not initially have.

Happy Holidays and 73

Michael,

Your very keen and want to learn lots which is admirable and the good people on this site will help, but sometimes are not able to answer questions immediately. I don't always get emails on a daily basis since the change by yahoo, then other days I may get a huge email dump of some 50+.
Because of your limited knowledge\experience with these radios, by going ahead with repairs that you're unsure of not only creates problems and is a waste of money for you , but it then introduces another problem to your already sick radio which could have been fixed a lot easier.

As such, I would like to recommend that you repair one radio at a time and if you insist on jumping between different radios please keep it related to the email header, eg; ts830 power, should be kept to the 830 issues, and not use the same header for the 530 HV issue, it becomes confusing and hard to keep track, even though there are some similarities to the 830 and 530 series. This is only my opinion and friendly advice.

Lots of the newbies or people who are learning keep these emails in respective order and this can create problems for them, which in turn makes it difficult for our guru's and friends.

Also some of us stick to repairing certain models\series and can offer advice which takes the pressure off Terry and Mike.

I am not scolding you or anyone else, just trying to give you a helping hand and prevent you from 1 damaging your radios further, 2 wasting money and resources and 3 hopefully prevent you from turning into a SK, becasue sooner or later if you keep going at it like a bull in a china shop, you'll touch the wrong thing.

As you suffer with limited sleep, my professional advice is to stay away from repairing your radios and anything that is pointy or sharp when your tired! Patience is a virtue and an absolute must with these radios.

Best 73's and very Merry Christmas to you and all on the forum

Dave

Nothing going on on the HV board, do you mean the Rectifier board?
Haven't checked any thing there yet, except the 470 ohm resistor that usually blows.
I replaced the big 500Volt filter caps for the HV supply.
Was getting low HV yesterday, it's the one fix that was suggested.

Couldn't repeat the tune today because iIstarted out with no IP right off the bat this morning.
I was getting 450volts on my meter of the Knwd TS-530S at the HV setting on meter, SG off, "I THINK". 450volts with SG on "I THINK" when trying to do a "neutralization".

Hi Michael,
How about if you take a clear picture of the HV board so we could see what’s happening ? (assuming you have a digital camera or similar)
73 and all the best for the season to everyone 8-)
Rob VK3BRS

From: TS-520_820_530_830@yahoogroups.com [mailto:TS-520_820_530_830@yahoogroups.com] On Behalf Of Michael SylvesterSent: Tuesday, 24 December 2013 10:39 PMTo: TS-520_820_530_830@yahoogroups.comSubject: Re: [TS-520_820_530_830] TS-830 power supply

Well, wonderful. Blew a fuse.

HV caps replaced. I did a neat job of it. Soldering and wiring I'm real good at, it's one of those mechanical things that comes natural to me.

I need to know if I have the polarity on the caps right.

If so I've got another problem.

Before I spend an hour pulling the caps and rewiring again I'll wait for conformation if I'm right or wrong....

I think I got it Bass ackwards and that's why I blew a fuse.

Could I get a reply from somebody that is familiar with

Ken/K4EAA's HV kit HV 150B?

(see post below that I'm replying to)

I geuss the "Breakfast Club" gets another day of boredom without my irritations, dangit!

Merry Christmas!

Michael///KD0WSJ

From: Michael Sylvester <sylvstrmchl@...>To: "TS-520_820_530_830@yahoogroups.com" <TS-520_820_530_830@yahoogroups.com> Sent: Tuesday, December 24, 2013 4:50 AMSubject: Re: [TS-520_820_530_830] TS-830 power supply

I'm replacing the HV caps in my TS-530S that quit during the ice storm with my crap Swedish Dipole.

I have one set of caps from Ken, K4EAA, "HV repair kit" HV 150B, Nichicon 150uf at 500V, 105*C.

The new caps are marked for polarity but it is ambiguous to me.

Short caps with a grey strip up the side that has 0 0 0 0 0.

I see the base of the contacts also has a checkerboard pattern, almost like a +++++.

40 years ago the only thing marked on electrolytics was the + side.

I'm going to assume this IS the + side with grey strip and 0 0 0 with post stamped with checkerboard ++++.

Is that correct? Stripe is still + side?

Old tall caps are marked with black dot on Neg side, Nothing else.

Hopefuly somebody replies quick OR I have it right, or both!

Going through "NO Radio" withddrawal.

Pretty bad, 8 radios and none working 100%

I'm sure the armchair pilots of the "Breakfast Club" are missing my daily political rants that always piss them off!

Hey, I got some sleep! 3 hours!

Tried to go through tuning to review what I remember and correct my buggered up statements from yesterday.....radio has no IP at first tune steps....

No harm done replacing caps. No signs of other damage, It's quick enough. It's also the only fix suggestion I got yesterday.

(Other than learning what I'm doing and watching my wording more closely,

Sg off, sg off...!!! hi...hi.)

Side note to Terry, I had a Heathkit DX-40 when I was 13 and a Novice, 42 years ago. Miss it. Also had a monster National 5TA1 receiver with pull out coil sets, total of 4.

I wish I had not made that sad drive to the dump with them 15 years ago. It still bothers me. Good old freinds that I let down....

"Merry Flippin Christmas"!! Enjoy your families.

Michael///KD0WSJ

From: W5RKL <w5rkl@yahoo.com>To: TS-520_820_530_830@yahoogroups.com Sent: Monday, December 23, 2013 9:35 PMSubject: Re: [TS-520_820_530_830] TS-830 power supply

Never use a pair of 450VDC capacitors to replace the KW hybrid HV filter capacitors! The resulting working voltage will be too low, 900VDC.The working voltage of each series connected capacitor, "adds" but the capacitance divides, the "opposite" of resistors in series! Therefore, with two 120ufd 500VDC capacitors connected in series, the total

capacitance is 60ufd (120 x 120 / 120 + 120 = 60) and the working voltage is 1000VDC (500 + 500 = 1000). If the KW hybrid HV filter capacitors are replaced with two 120ufd 450VDC capacitors, the total capacitance would still be 60ufd BUT the working voltage would only be "900VDC" (450 + 450 = 900) which is too low for the KW hybrid's HV supply's no load output voltage! Filter capacitors that are connected in series, should be the same capacitance value and the same working voltage rating. The working voltage of each capacitor should, when added together, exceed the "no load" output voltage of the power supply. When connecting capacitors in series, it is highly discouraged to mix capacitors of different capacitance values, even if the voltage rating of each capacitor is the same. When capacitors are connected in series and AC voltage is applied to the capacitors, the AC voltage pays no minds to the capacitor's high internal resistance but rather divides the AC voltage inversely proportional to the capacitors capacitance values even with equalizing resistors connected across each capacitor. That means you should not connect an 80ufd capacitor in series with a 150ufd capacitor even if both capacitors have the same voltage rating.Equalizing resistors connected across each series connected capacitor, each resistor has the same resistance and wattage rating. The resistors act to equalize the voltage across each capacitor plus serve as bleeder resistors to bleed the capacitors to zero when voltage is removed. Each series capacitors charges "individually" throughout the AC sine wave cycle but discharge as a "single" capacitor.73Mike W5RKL

After 22 years of enjoying this rig I have decided to part with it. It was overhauled by Ken K4EAA in 2009. The receiver is still strong but it has developed low power output problems, and sending it to the USA again for work is an expensive proposition.

So I will take offers.. Photos and more detail on the radio can be had sending email to ve5zg at rac.ca

Greeting Group!

  Well, another year is about to come to a close. This group has done well. We have

many new members and, some changes in the group's "administration." So, let's please remember why we are here....to further the preservation of these wonderful old rigs, and to further the enhancement of the Amateur Radio Community in general. Please be respectful of, and to, other members.

  So, to all members of the group..... Happy Holidays!

  Also, to the men and women of our military services, no matter where you may be, we appreciate
your service, and wish that you could be with your loved ones instead of on the other side of the worldor, where you happen to be, other than with your family. Many have sacrificed themselves so we can be here today. So, next timeyou see a military person...give them a quick salute and, tell them thanks! It will make their day!

  Thanks for your time...........

There is a generator board here:
http://www.ebay.com/itm/Nice-Functional-Kenwood-TS-520-Generator-Board-/291041216313?pt=US_Ham_Radio_Transceivers&hash=item43c3688739#ht_59wt_888

This fellow has a couple boards but doesn't
identify them for $25 shipped:
http://www.ebay.com/itm/Kenwood-TS-520-Miscellaneous-Parts-Free-Shipping-Con-US-/161103253328?pt=LH_DefaultDomain_0&hash=item2582808f50#ht_2067wt_888

Kenwood ts-520 parts search:
http://www.ebay.com/sch/i.html?_odkw=kenwood+ts+parts&_osacat=0&_from=R40&_trksid=p2045573.m570.l1313.TR0.TRC0.Xkenwood+ts-520+parts&_nkw=kenwood+ts-520+parts&_sacat=0

Just do a search for ts 520 or ts-520 or Kenwood
parts....when you find an item, go to that persons
"store" or click on "see other
items".
Hope this helps.
Michael///KD0WSJ

The "New topic" window is not working for me.
Twice today the send button didn't function. Had to copy
and paste back here.

I don't know of a sourece in the UK but I use

www.vacuumtubes.net

They have both, NOS and "Chinese" 6146s, your choice. I pick "NOS" and have never received a bad tube from them. I purchased six 6146As 4 years ago, all used in my Heathkit transmitters/transceivers and they all are still in service today, working very well.

Ron:

If you cannot find a probe tip then buy an adapter. Can get un-terminated and 50 ohm terminations. Screws on probe body and then connect a BNC to mini-grabber test lead to it. Works just fine as usually cant get probe tip into high density areas of the KW boards and at frequencies involved dont need to be too concerned about lead inductance/capacitance effects on your readings. Hi Michael,
In the past I worked with two guys on two useful projects.

The first (I'll call him "N") would patiently discuss every aspect of the problem to be solved until he was confident he understood the problem completely.

The second (I'll call him "R") had a similarly brilliant mind, and had his invention worked, he would now be wealthy beyond imagination.

"R" lacked patience to understand the nature of the problem he wished to solve.
It was not his nature to slow down and think. He believed he could short-cut natural law by constant activity. He often said, "Let's get on with it."

"N" was successful - his project (a machine worth near $1 million) continues to work after 30 years - 24 hours per day.

"R" was unsuccessful - even though his project was not more complicated than "N's" project.

I learned a great deal from watching these two fellows.

I came to understand the difference between directed thoughtful energy and undirected energy.

With electronics the careful observer finds the tricky faults - the faults that others miss.

In the end, "make haste slowly" wins. I learned this from "N".

The principle applies in TS-520 (etc) maintenance.
This list is crowded with postings (and questions) from fellows who take short cuts rather than spending the time to understand the working principle of the "instrument" on the bench before them.

I worked for many years with "N", and he taught me many things, but the greatest thing I learned from him was to observe carefully and think deeply.

Well, here's a big project. I aquried a non-functional TS-820 that's completely dead. No receive/transmit, relays, audio or digital display. The VFO jumper is installed. High and screen voltages are present. Upon checking the low voltage power supplies, I found the 14-Volt rail low. I replaced C1 and C2 on the relay circuit board and this brought it back to 14.5 volts. Now the problems found with the +9 volt supply. Found Q7 (2SA496) shorted. Replaced using a NTE-184. Q4, Q5, Q6 and D5 checked OK. Now, here's the issue. Adjusting VR4 effects no change in setting for 9-volts out. Sits at about 6.7 volts. Remove the load and output jumps to around 12 volts. I also found the 5 Volt regulator and series 5.6 ohm resistor supplying display power open and replaced those. Still no display.

Wonder what's with the 9-volt supply ??

Michael,

I do not know where you got your HV caps from but, the shrink wrapping on the outside indicates where the "neg" lead is. I can not understand how you figured it was a "zero." Also, the positive or "+" terminal is usually marked(stamped) on the bottom of the respective terminal. I suggest that you do slow down. One of these days you may electrocute yourself..or do other serious harm to you and or the rig under repair. This group is not intended, or designed to be a quick and or easy answerto anyone's questions.

Jim:

How hot is the series pass heat sink getting? Can you leave finger your on it?

What is the load resistance from AF-1 Pin 1 White/Org wire to chassis ground in RX mode with the power off? Should be approx 85 ohms.

You can carefully release White/Org load wire at Pin 1 by depressing lock tab with sharp pointed tool (I use tip of soldering aid) and place ma meter in series to measure the load current. Should be something on order of 150ma in RX mode.

If you unplug AF-1 and feed regulator with bench 14vdc (or jumper in the rigs 14vdc) and place 100 ohm dummy load resistor from 9vdc pin to chassis ground can you vary the 9vdc regulated with VR-4?

Jim:

I forgot to ask what RF-1 is doing.

Of course you need to find and fix cause of low 9vdc regulated, but where is RF-1 voltage at? RF-1 is the AGC/ALC bus reference voltage and should be approx 3.5vdc. With 9vdc regulated approx 2 volts low then RF-1 is going to be pretty low so the AGC bus which supplies the dc control voltage to all the gain controlled dual gate mosfets on the IF and RF board will be quite low making the receiver sensitivity low.

If RF-1 is too low then there will be no RX due to the gain controlled stages being cut off.

Blank display typically means PLL unlock which means you will have no VCO signal. With no VCO you will have no LO at the RX and TX mixers on the RF board so no RX (no RIF signal) or TX function (no TX drive to 12BY7A control grid).

One cause of PLL unlock is loss of VFO output. With less than 7vdc supplied to the VFO its rf output level will very likely be too low to produce the mixing required for VCO signal. I seem to remember of VFB gets much lower than approx 6.5vdc RX and Display are dead.

So of course first objective is to restore 9vdc regulated to normal. If you get normal 9vdc should be able to adjust RF-1 to normal level and most likely will get your RX and display back. .

> grey stripe with 00000 down the side of the cap, THE NEGATIVE LEAD.

Those zeroes I suspect all have a "dash" inside them... If you stop looking so hard at the circle, and start looking at the dash, you might start seeing the minus sign on a round field that means 'negative' pole.

I am looking at a couple of electrolytics marked precisely this way. The "zero" part is just a field, plain and empty, on which to stamp the minus sign.

If I squint I can see where you got confused. But forty or fifty years of mucking about with this crap, I'm used to it.

(Anyone else remember 'stop-light' markings on square, flat-pack capacitors in old TVs and radios? Six circles, two rows of three, coloured dots in 'em. All sorts of other kinds of part markings, none of them compatible with the others...)

Michael S.,

Best of luck with your unorthodox approach to radio repair. In the 60's at my
high school there was a sign that said "Experience keeps a dear school, but some
will learn no other way." That's basically what you've told us about yourself. If I were one of the gurus here (which I'm not), why would I spend my time drafting a careful response to one of your queries when it was anybody's guess whether you'd wait long enough to receive it or whether you'd charge ahead on your own?

What you've said in you last email was, "Thanks for your help, but there's no guarantee I'm going to listen to you." I don't think this is a great way to find mentors willing to help you.

You report a number of less than optimal growing up experiences, but don't seem to grasp that atypical experiences may lead to atypical behaviors, but these may not be successful or heroic. One of my mentors told me that if I couldn't be perfectly normal, maybe I should act as if I was. I can't say that I've become healthy, but acting as if I am has allowed me a lot of benefits. But I can't, I guess, expect others to understand that . . . .

Very Best Regards,
Roy Kersey

The good thing about taking this approach to hybrid radios is that one way or another, you're only going to do it once...

Merry KZZZZRRTT-mas from the blue (but bloody cold) seas and sandy beaches of the east coast. No, I'm not going swimming.

Yup, Bob’s right. You started seeing minus signs on caps back when Japanese components became more common. There was no plus sign in their “alphabet" at the time

I don't know exactly who I'm responding to, Robert or Gordon, But here's the run down. First paying job, night freight (mostly canceled checks) 10 legs per night, Denver to Kansas City through Nebraska, Aero Commander 500B. Then, 4000 hours SA226 Metroliner(Air Midwest), B-727 100,200 (Air One), DC-9-10,30 (Midway), on to PSA (wonderful airline) DC-9 Super 80 (MD-82), DC-9-30. PSA merged with USAir/ways in 1988. Flew the B-737 300,400, B-757, B-767 international. Never made it to EGPF, USAirways added Glasgow after I retired. There you have it. Contact me off net (QRZ email is correct) and we can ragchew about airplanes and Kenwoods. What could be better? Maybe F/As. Thanks for asking.
Best regards and 73,
Butch Lewis
KØPSA (for the airline)

Bob and others:

I am not trying to defend Michael, but what I believe he is using is the Nichicon Black case Type GN HV caps that Ken Kempski K4EAA sells. These have snap in terminals and if you have little experience and hurry your work and do not have a questioning attitude easy to put them in wrong.

Take a look at this data sheet. Look at the photo of the cap. There is no photo of the terminal end which would help. The polarity band on the case as most of us know by convention identifies the negative terminal so it doesnt matter if it has Os or Zeros or Minus signs imprinted on it. All we really need is the stripe or band to denote the negative terminal. We dont need any markings within the band. It just so happens that it has oblong circles which are symbols for a negative or minus sign. Look at the picture and you can see the polarity stripe with the oblong minus signs imprinted on the vertical band.

As I said an experienced tech would know without asking that this is the minus terminal of the cap. If you look at the drawing of the terminal post you will see the the negative terminal is nearest to the polarity stripe that extends to the end view. Again pretty standard stuff.

However, there is some confusion in actual practice if you look at the round rivet head as it comes with a cross hatch pattern imprinted on it that could be miscontrued as positive symbols. If you take a quick look you might think it was a Plus sign for the positive terminal. That makes no sense as it is the terminal closest to the negative polarity stripe. The first time I used these caps I had to stop and think about it. There is no polarity marking on the positive terminal which is opposite the polarity stripe on the can. I dont know why the negative terminal doesnt have a minus sign or black paint dot which would be more typical.

Perhaps the production run of caps that Ken sells are a factory mistake. Maybe the cross hatched rivet was intended to be used on the positive terminal and was installed at factory on the negative terminal? This would eliminate any confusion as the crosshatching does look like plus signs.

So in Michaels defense the cross hatch pattern on the negative terminal is where the confusion came in. No minus sign on it and no black paint dot on it. It is just located close to the polarity stripe on the case.

If you buy the Black PTE case caps from Ken just make sure you connect the terminal closest to the polarity stripe to negative regardless what marking it has imprinted on the terminal rivet head. If you get the Blue PTE case caps there is virtually no way to reverse them as the Positive terminal has one large Plus sign imprinted on the rivet head and the Negative terminal is closest to the case polarity stripe.

I think we have beat this to death.

Greetings Group,

Thanks to Terry-K9TW, and others, for your observations and input regarding this subject. I have obtained replacement HV caps from Ken-K4EAA and "other sources" and have not had a problem identifying the "neg" terminal...maybe lucky? The problem being members not being able to follow instructions given, AFTER asking for help, disregarding safety protocol(s)...and simply saying...thanks for the help...but I'm gonna do what I want. This group is not about that. There are group members that are very knowledgeable about troubleshooting, diagnostics, repair...or any other term you care to apply, regarding the KW hybrids specifically and, electronics in general. If for some reason(s), you have difficulty abiding by the group's policies/rules...please let any of the "moderators" or "co-owners" know and, we'll be happy to grant your request to be removed from group participation .

I am trying my best to maintain the intended spirit and function of this group. I must say that recently, it has tried my patience, and my willingness to "not over-moderate," but I am attempting to keep this group functional as to purpose. So that being said:

As Mike-W5RKL stated prior: This topic is closed!

So...to all...have a great rest of '13 and let's strive for a better '14

>However, there is some confusion in actual practice if you look at the round rivet head as it comes with a cross hatch pattern imprinted on it that could be miscontrued as positive symbols. If you take a quick look you might think it was a Plus sign for the positive terminal. That makes no sense as it is the terminal closest to the negative polarity stripe. The first time I used these caps I had to stop and think about it. There is no polarity marking on the positive terminal which is opposite the polarity stripe on the can. I dont know why the negative terminal doesnt have a minus sign or black paint dot which would be more typical.
>
>
>Perhaps the production run of caps that Ken sells are a factory mistake. Maybe the cross hatched rivet was intended to be used on the positive terminal and was installed at factory on the negative terminal? This would eliminate any confusion as the crosshatching does look like plus signs.
>
>
>So in Michaels defense the cross hatch pattern on the negative terminal is where the confusion came in. No minus sign on it and no black paint dot on it. It is just located close to the polarity stripe on the case.
>
>
>If you buy the Black PTE case caps from Ken just make sure you connect the terminal closest to the polarity stripe to negative regardless what marking it has imprinted on the terminal rivet head. If you get the Blue PTE case caps there is virtually no way to reverse them as the Positive terminal has one large Plus sign imprinted on the rivet head and the Negative terminal is closest to the case polarity stripe.

The +9 volt regulated supply is now up and running. It really helps to use the right pass transistor. I put a NTE-184 (NPN) instead of the correct NTE-185 (PNP). Dumb mistake.

Now, as far as the 3.3 volt RF-1. It's sitting at +13.6 volts. Unplug the IF3 connector on the IF board and drops to around 3.3 volts at the AF-1 board.

If you unplug IF-3 on IF board what voltage do you then have on Pin 8 on the exposed board connector pin? If you have 13.6vdc on RF-1 Pin 8 then you have a fault from the 14vdc supply to your AGC bus. I have never seen this.

Only source of 14vdc other than shorted series pass is a shorted dual gate mosfet in one of the four gain controlled devices. Drain would have to be shorted to Gate 2 of Q1, Q2, Q3 IF amps or Q2 RF amp. The AGC bus feeds those four active devices that have 14vdc Drain supply.

RF-1 also feeds the ALC bus but that should be out of the picture in Rx mode and no source of 14vdc from the ALC circuit

One thing that's going for us when we try to repair these things is that it once worked.

After removing the IF-3 connector, ,there is about 140mv on the exposed pin #8 on the board.

The digital display is on and with the band switch set to 40m, it reads "9.111.1".

Topic: 46669 Message: 46699

That is good. Should never be 14vdc supply on the AGC bus back feeding RF-1. Should be no source of 14vdc on any pins on IF-3?

So as I understand your previous post you said that you had normal RF-1 at the AF-AVR board with IF-3 unplugged and with it plugged in then you had 13.6vdc on RF-1? As I said that is very rare if not unheard of.

Have you repeated this measurement? If you find you now have normal RF-1 with IF-3 landed do you now have receive mode? If you turn RF gain full CCW does the S-meter deflect full scale? If so that is telling you that RF-1 at AVR board is making it to the IF Board and AGC bus is energized to proper base level (full RF gain)

Work on getting RX mode and then can work on digital display.

Do that by making sure you have normal 9vdc and RF-1 voltages at the AF-AVR board. These two voltages along with 14vdc are required for RX mode.

If dont have normal RF-1 (3.3 to 3.5vdc) wont have AGC or ALC bus and no RX and TX modes.

From: <famtech@...>
Topic: 46669 Message: 46700

First of all, thanks for all the valuable input. So far and in review, here's where things stand. I replaced the two low voltage filter capacitors, the shorted 9-volt pass transistor, the open 5-volt 7805 regulator and it's open series dropping resistor. With all connectors plugged into their respective circuit boards, these voltages are measured. The 14-volt supply measures +13.8. The 9-volt supply is set at +9.01 volts. The 5-volt supply for the display is at +5 volts and the 5-volt supply on the relay board is at +5 volts. The RF-1 voltage is at +12.2 volts. Pulling the IF-3 connector from the IF board drops the RF-1 voltage down to +3.3 volts. With the IF-3 connector un-plugged, pin-8 on the IF board is next to zero. With the IF-3 connector plugged into the IF board but with the RF-1 wire floating, pin-8 is next to zero but there is +12 volts measured on the RF-1 line. There is no S-meter action. No audio or "hiss" from the speaker. The receive/transmit switch does nothing or any of the other controls for that matter. The S2001A finals and 12BY7 are originals and test fine. Overall condition of the rig is an eight.

There is a fellow on Ebay selling TA7201P amp IC's in case anyone is interested. Item #565827260135. Heard these devices are no longer being made.

Regards,

Jim L.

What do you mean by the RF-1 lead floating? Have you released the lead from the IF-3 plug body?

If so, you are telling me you have approx 12vdc on it coming from the AVR board in an unterminated state ie no load on it. In unterminated state it should have approx 9vdc on it and not 12vdc. Whatever is on the Collector of Q7.

Try connecting a 10k to 15k resistor from the free end of RF-1 lead at the IF board to chassis ground and then measure the voltage. It needs a dummy load on it to be able to adjust VR-1 to produce 3.3 vdc.

Maybe what you have is a bad molex connector interface at IF-3 Pin 8 or a bad solder connection at Pin 8 so the AGC bus is not being fed thru R66 2.2 meg resistor. If RF-1 is really open circuited with IF-3 plugged in you will have no AGC bus voltage and Rx will be dead.

What do you have to measure the AGC bus with? Need minimum of 11 meg input Z meter.

If you have a 3vdc battery (couple of flashlite batteries in series) connect the negative lead to chassis and plus lead to AGC Pin 11 and see if Rx comes alive.

Hi,
This is my first note to the group, I hope I am sending this to the right place...
I am looking to use my HeathKit paddle Keyer on my ts520s.
I saw in an older letter the group about it, and he made it sound like you just
plug it in the back of the radio with a good wire setup.
Am I getting that right? or do I have to change things in the keyer?
I hope someone can fill me in on using this paddle keyer.
BTW. I have been looking at this group for over a year now, and it has to be the
best place for any info on older Kenwood radios! You guys Know your stuff!!!
I have a ts520s and I LOVE it.... Everything is working right now and I have made some great calls with only a g5rv jr. I cant tell you how much I have learned about my rig from the letters I have seen here....
I hope some one can fill me in on this paddle setup. I would love to use it on my 520s....
Thanks for the help.....

> Am I getting that right? or do I have to change things in the keyer?

I am not absolutely certain, having never done it myself, but I think they just play together out of the box.

You can hook up the "Receiver Audio" jack on the back to the rig audio out and listen to the sidetone of the keyer as well as the radio audio through the headphones plugged into the keyer. THAT bit I know for sure, it worked really well on an HW-8 with an HD-1410 keyer. (My fist is all thumbs, I don't use any kind of bug or electronic keyer. Straight key for me, only, I'm a Morse KLUTZ as it is.)

But as for connecting the keyer, as I said, I've not done that, so do NOT take my advice on that. My --guess--, looking at the manual, is that they just plug together, but DON'T take my word for it.

What I can offer for sure is a truly pristine copy of the builder's manual as a PDF file. You didn't specify a model, so I'm assuming it's an HD-1410. I have that model builder's manual, complete, except for the schematic. I think I can even find that if you need it, as well, or perhaps point you to where you can grab it yourself. I have a LOT of files gathered over the years, I'm a digital pack-rat.

Contact me off-list if you need the manual.

Wayne,

You didn't say which Heathkit keyer you are referring to. The HD-10 and HD-1410 keyers both will work with any of the KW hybrids. I have no experience with the Heathkit SA-5010 micro keyer so I won't comment on it.

The HD-10 has a maximum negative keying voltage rating of -105VDC at 30ma. The HD-10 is not an Iambic keyer.

The HD-1410 will key both positive and negative keying voltages. The maximum positive keying voltage is +300VDC at 200ma and the maximum negative voltage is -200VDC at 10ma. The HD-1410 is an Iambic keyer. An Iambic keyer allows you to "squeeze and release" the paddles to form characters. This takes a lot of practice. This does not mean you can't use the HD-1410 keyer with the KW hybrids. It simply means you have to form the characters yourself using the dot and dash paddles individually. The paddles are connected internally during assembly based on whether the operator is left or right handed. You can change the paddles from right to left handed or vice verse by simply removing the power cable from the rear panel, remove the cabinet top, and swap the paddle wire connections, there are 2 of them.

There are no internal "jumpers" to change. There is a mechanical adjustment in both keyers that sets the paddle "travel" distance. This adjustment is made on the HD-10 by loosening the "micro switch" mounting bracket screws on the bottom of the keyer the move the brackets to the desired setting. The HD-1410 has a similar paddle travel distance adjustment but is much easier. Remove the power cable, remove the top cabinet, then loosen the screw on the "Black" blade you see on top of the paddles. This allows you to move the blade left or right to shorten or lengthen the paddle travel distance between the paddle contacts. Adjust the blade to the desired distance then tighten the blade screw. Power up the keyer and check the paddle operation. If it is okay, replace the top cover and tighten the side panel screws. If the paddle travel needs adjusting, simply repeat the process until you have set the paddle travel according to you liking.

Connecting the HD-10 or HD-1410 keyer to the KW hybrids is very simple. I recommend using shielded keying cable. I use VCR/DVD interconnecting cable. A 1/4" mono plug is required for on one end so it can be plugged into the KW hybrid's CW key socket, check your local Radio Shack they may have it. You can use a stereo 1/4" plug, just use the "TIP" and "SLEEVE" connections, leaving the "RING" connection unused. The cable's center conductor wire is connected to the plug's "Tip" and the shield is connected to the plug's "Sleeve". This is required for either keyer. If you are using the HD-1410, leave one end with an RCA plug attached.

Connecting the opposite end to the HD-10 keyer, connect the "center" wire to "KEYED LINE" terminal and the shield to the "Ground".

Connecting the HD-1410 to the KW hybrid, simply plug the RCA plug into the HD-1410's "KEYED OUTPUT" socket on the rear panel of the keyer.

The HD-10 has a "Weight" control, accessable through the center of the "SPEED" knob (knob on the left). A narrow blade screw driver is required to make that adjustment. Hold the SPEED knob so it does not rotate then adjust the WEIGHT control using the screw driver to the desired setting.

The HD-1410 does not have a weight control.

The HD-1410 SPEED knob, when pulled out, makes the keyer have a constant "Key" on the "KEYER OUTPUT" socket, allowing the transmitter to be keyed "continuously" as long as the SPEED knob is pulled OUT. Pushing the SPEED knob "IN" removes the constant key at the KEYER OUTPUT socket.

The HD-10 has a similar constant key control but it's on the POWER switch. Move the POWER switch fully to the right will result in a constant keyed output. Move the POWER switch to the middle will remove the constant key at the keyer's output.

That's all there is to connecting and using either keyer with your KW hybrid.

One word of advice. A keyer will not make you send good CW if you have not learned the code and have practiced to achieve good rhythm "first" using a straight key. I have heard all the stores, "a keyer will make you sound good..." Nope, not until you learn rhythm using a straight key FIRST then learn how to put that rhythm to use by learning how to "properly" use the keyer paddles. This ALL takes plenty of "Practice" and you won't learn it over night, over a weekend, or even in 6 months. I have been sending and receiving CW for over 47 years, 22 of which were as a Navy Radioman and Navy CW instructor. I've heard very good fist but I have also heard some very lousey/horrible fist. You should listen to the ARRL machine CW (computer generated) and practice sending so your fist sounds the "same" as the ARRL machine CW. Listen to the rhythm the machine code makes, that should be the goal you should practice for.

Til: 'TS-520_820_530_830@yahoogroups.com'
Emne: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Mike,

I did perform voltage test after I replaced the four cathode resistors. Voltages were according to specs. Then I plugged in the new final tubes. Again bias and screen voltages on FG and SG on the final unit board were according to specs. Then I switched on the HEATER and after a few minutes the SG SWITCH as well. Voltages still normal, no smoke, no unusual sounds. It was not until I keyed the transmitter and started the standard bias adjustment procedure that the cathode resistors opened. I did no more than that.

The finals (6146W JAN) were shipped from RF parts through a local shop and arrived yesterday. They are unused/new and quite expensive. If they are bad and have shorts, I will naturally lodge a complaint. But how to prove they were bad on arrival?

Peter,

You should first think what "difference" or "change" has occurred since you replaced the 4 cathode resistor then performed the voltage measurements/test? The only change you have indicated is you replaced the

6146B final tubes. Yes, I said I didn't trust the original tubes, still don't, but now I don't trust the replacement tubes you used either! I suspect there are possibly shorts in the replacement 6146Bs which caused significant increases in voltage, current, and power dissipation in the cathode circuit with the replacement 6146Bs installed.

You should understand the 6146 has a "Beam Forming" plate that is connected both internally AND externally to the tube's "Cathode". This is required so the Beam Forming plate has the same potential as the Cathode, "negative in respects to the plate". So any short to the Beam Forming plate is also a short to the Cathode.

You can perform the calculations yourself, to see what happens when element short internally in the tube. All the voltage and resistance values you need to perform the calculations are shown on the final amplifier's schematic. The following is an example if a short occurs between the 6146 screen and beam forming plate/cathode and it clearly shows what voltage, current, and power values will be in the final amplifier's cathode circuit.

For example, if the screen shorts to the beam forming plate, the cathode voltage would "instantly" become "+265VDC" which will result in "53 amps" of cathode current (265 / 5 = 53) and 14,045 watts dissipated in the cathode circuit (53 x 53 x 5 = 14045)! That would result in 13.25 amps flowing through "each" 20 ohm 1/2 watt cathode resistor (265 / 20 = 13.25) and each cathode resistor dissipating 3,511.25 watts (13.25 x 13.25 x 20 = 3511.25).

73
Mike W5RKL

On 12/21/2013 7:26 AM, Peter Ravn wrote:

Mike,

I had carefully followed your instructions and was now ready for the final test with a new set of 6146s plugged in. When I was adjusting the bias with the pot on the rear panel, there was a hardly audible crack. The meter said 60 mA, when I turned off the radio and started looking for a cracked resistor. I found none, so the crack might have come from somewhere else in my room. But when I resumed the bias adjustment, there was instantly a loud crack and a flash. I powered off the 830s immediately.

Upon closer inspection four cathode resistors on the final unit board were open. They had worked as fuses and hopefully saved the finals. In the morning I had replaced the old cathode resistors with new ones with the same specs, so why did they open?.

Peter,

That's great to hear your 830 is coming back to life.

You said the plates turned RED in the 6146s. You don't know what damage may have occurred in the tubes when that happened. You said with the tubes removed there is no smoke and no unusual sounds. You also said the voltages are changing as they should when testing between receive and transmit, at least that is what I got out of what you said. Therefore, that's why I would not use the original tubes. It's also possible the original tubes themselves may have caused some or all of your problems.

73
Mike W5RKL

On 12/19/2013 12:32 PM, Peter Ravn wrote:

Mike,

Good news! My TS830S passed the first tests with driver and final tubes removed. No smoke or unusual sounds. Bias voltages run smoothly from - 40 VDC to - 110 VDC on FG. Screen voltages are + 265 VDC on SG. The panel meter works normally again, and so does the receiver. The next and final test will be with tubes installed.

I am waiting for the final cage kit from KE7OAY, and tomorrow I will have a new set of 6146B□s to replace the ones that turned RED. You stress that I should not reuse the same tubes. Why not?

Thanks a lot for your outstanding help.

Mike,

I have ordered The Final Cage Repair Kit (C7, C8 and L1) from KE7OAY. When it is installed, and R11, R15 and R16 on the rectifier have been replaced, I will follow your instruction and let you know the result.

Peter,

I made a couple of mistakes.

First, I gave you the wrong final amplifier tube socket pin number to measure the final tube's screen voltage, it should be pin 3 instead of pin 5.

I also left out, accidentally deleted it, where I asked you to check the bias voltage at the final amplifier's tube socket, pin 5, You should measure the grid voltage in transmit and adjust the bias pot. You should see a smooth increase and decrease in bias voltage on pin 5 of the final tube socket when adjusting the bias pot.

Ken, K4EAA, sells an RF amplifier rebuild kit that has the small RF choke along with a few other components. Check his website for prices, www.k4eaa.com .

Sorry for the mistakes.

On 12/11/2013 12:30 PM, Peter Ravn wrote:

Mike,

This is what I found today. I rechecked the inside of the final amplifier and found no obvious signs of overheating. I measured the big RF choke (L2). Unplugged it was 0.9 ohms and 137 uH. I lifted the small RF choke (L1), which was 0.5 ohms and only 0.035 uH instead of 470 uH. To be absolutely sure I repeated the measurement five or six times. So apparently L1 has gone bad and should be replaced. The thing is how to get it.

In the RF unit I checked resistors R6 and R7, and they are ok. I also checked C181 and C182 in the IF unit. One was 27 uF, the other 18 uF, so they seem ok. In the rectifier R15 is 60 K and R16 70 K. They should be 57 K and will be replaced together with the infamous R11, which suddenly looked overheated though not open.

To be continued

Emne: Re: SV: [TS-520_820_530_830] TS830S no bias

Hi Peter,

You said you checked the inside the final amplifier. Did you visually inspect the 2 RF chokes in the final amplifier? There are 2, the large vertical choke between the 2 final tubes and small choke on the chassis near the final tube sockets, it looks like a resistor. It's on the top of the final amplifier section of the chassis.

Also, do you have a known good pair of 6146Bs? I wouldn't trust the ones that were in the 830 when the smoke and RED plates occurred. If not then obtain a known good pair of 6146Bs to replace the old 6146Bs.

I recommend you leave the driver and both finals out of the 830. Make sure the final plate caps can't touch/short to anything, then connect a DC volt meter's Black lead to the Final Unit's "FG" terminal and the meter's Red lead to the chassis. Set the DC volt meter to measure a minimum of 200VDC. Set the Mode switch to USB or LSB, and power up the 830. If any abnormal noise are heard or you see smoke, turn the 830 off immediately and locate the source of the noise/smoke and fix it before proceeding. If everything appears normal then flip the SEND switch UP and note the bias voltage on the DC volt meter. Rotate the bias pot either side of center rotation, you should see a smooth increase and decrease of the bias voltage. Unkey the transmitter.

Repeat the test except this time you will be measuring the final tube's screen voltage on pin 5 of the final tube socket. You should see approximately +265VDC. The screen voltage will not change much, if at all, when you switch from receive to transmit then back to receive. This is because there are no final tubes in the final amplifier so screen current will flow in the screen circuit. Unkey the 830 and power the 830 OFF.

If there are no problems encountered during the above test, proceed to the next test. However, as I said above, if there are any problems encountered do NOT proceed with the next test, determine the cause of the problem and fix it before you proceed.

Set the SG switch to "OFF", power up the 830, and note the final tube screen voltage, pin 5 on the tube socket and "SG" terminal on the Final Unit. The voltage should be approximately "-100VDC" and the Relay RL1 on the Rectifier Unit should be energized. Power the 830 OFF and set the SG Switch to ON and repeat the final tube screen voltage check, it should be approximately +265VDC and Relay RL1 on the Rectifier Unit should NOT be energized.

If those test/checks are good then power off the 830, let the HV filter capacitors bleed to zero (check HV caps with a DC volt meter) then install the driver and a pair of "known good" 6146Bs in the final amplifier.

Set the SG switch to OFF, power up the 830, and set HEATER switch to ON. Allow about an minute for tube warm up. Look and listen for any abnormal noises and smoke. If you see and/or hear any smoke and/or abnormal noise, power the 830 OFF immediately and locate the source of the problem and fix it before you proceed.

Set meter switch to ALC, CAR knob full CW, DRIVE control to 12 o'clock, band switch to 7, and SEND Switch UP. Again, if any problems such as abnormal sounds, smoke, etc., are seen/heard, turn the 830 OFF immediately. If no problems occur, adjust the DRIVE control for a peak indication. If meter pegs full to the right, reduce the CAR Control CCW so the meter pointer is pointing at or near 12 o'clock and continue adjusting DRIVE control for a peak ALC meter indication. Again, if any problems occur, regardless of what those problems may be, unkey the transmitter immediately!! If the problems continues, you smell something getting hot or you see smoke, power the 830 OFF immediately and determine the cause of the problem and fix it before you proceed any further.

Measure all final tube socket and Final Unit voltages on the "foil side" of the Final Amplifier Unit. Attempting to measure the final tube's screen and grid voltage through the top of the tube sockets can easily result in your hand/fingers and meter probes coming in contact with the HV on the RF choke and the plate cap parasitic suppressors. Use caution when measure DC voltage, as you know there are voltages in the 830 that can easily kill you so take your time and pay attention to what you are doing. Do not attempt to perform any of these test/voltage measurements when you are tired.

On 12/10/2013 12:03 PM, Peter Ravn wrote:

Mike,

I carefully followed your instructions, and this is what I have found:

All four cathode resistors in the final unit are within specs: R2 22 ohms, R3 21.7 ohms, R4 21.7 ohms and R5 20.9. They didn□t look overheated either, so there was no need to replace them. But the screen resistors looked somewhat bleak. R7 was 119 ohms and R8 109 ohms, so they were replaced. I carefully inspected the board and found no smoking gun. Finally I cleaned the board on both sides and replugged it.

With my ohm meter I spotted the erratic behavior of the bias pot you mention. After a careful cleaning the pot now shows smooth change of resistance when rotated. The resistance is now also identical on both terminals.

I opened the final cage and removed the final tubes. In the cage there was no sign of overheating. I also removed the driver tube.

On the reticifier R11 survived the battle, but with clear traces of overheating.

This is status until now. I will continue the troubleshooting as soon as I find time.

Emne: Re: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

It appears the bias pot is the source of instability when setting the 60ma idling current.

Unplug the main power, make sure the HV caps have bled down to zero before you attempt any of the following checks and cleaning steps.

Before you perform the following cleaning and testing process, thoroughly check the Final Unit's Cathode and Screen resistors. If there is evidence the resistors are damaged (overheated) or any of the resistors are out of tolerance, replace all of them. For example, if you find 2 of the 4 cathode resistors have overheated, replace all 4 of them with new resistors. The same for the screen resistors, if one if bad or out of tolerance then replace both with new resistors.

Thoroughly clean the bias pot with contact cleaner. Exercise the pot throughout it's travel, many times, during the cleaning process. I use DeoXit F5 Fader cleaner for pots then I use canned air to remove all cleaner residue and any dirt from the pot. I then test the pot using an ohm meter connected between the pot's wiper (center terminal) and any of the outside terminals. I rotate the pot slowly watching the ohm meter to see if any position results in erratic behavior. If I see erratic behavior I clean the pot again, thoroughly then retest the pot. Once the pot exhibits smooth resistance changes I consider the pot clean.

Remove the Driver and both Final tubes and make sure the plate caps cannot touch anything or short to the chassis etc.

You should use an analog DC volt meter for the following test. The meter should have a low voltage setting of approximately 200 to 250VDC. Set the meter to either low voltage setting, which ever your analog meter has.

Connect the analog DC volt meter to the Final Unit's "FG" terminal and ground (RED lead to FG terminal and BLACK lead to the Chassis). With you finger on the main power switch, power up the 830. If you see smoke or hear unusual sounds turn the 830 off immediately and find what is causing the smoke and/or unusual sounds and eliminate the problem before proceeding. If there is no smoke and no unusual sounds, continue on to the next step.

Set the mode switch to USB or LSB and set the SEND switch UP. Again, any unusual sounds or you see smoke, unkey the 830 and turn it off immediate. If all is okay so far then adjust the bias pot while watching the analog DC volt meter. The meter indication should rise and fall, depending on the direction you are rotating the bias pot indicating a smooth change in voltage as you rotate the bias pot. If this occurs, move the analog DC volt meter RED lead to pin 5 on the final tube socket foil side of the Final Unit PC board and repeat the bias pot adjustment, watching the meter closely, especially noting the volt meter movement at the low negative level of bias voltage, i.e., around the -50 to -70 VDC range. You should see the same results, a smooth increase and decrease of the bias voltage. If this test indicates a smooth change in bias voltage, no instability in the bias pot voltage indicated on your analog DC volt meter, then the bias circuit is working properly. The test results should be achieved using the analog DC volt meter connected to the AF Unit's "FG" terminal. The AF Unit and Final Unit "FG" terminals are connected together with a wire in the wiring harness. You can see this on the 830 schematic.

Do not reuse the same 6146 tubes, obtain known good 6146Bs.

Let us know what the results of the above tests are.

Peter,

You also might check the RF Unit's voltage divider resistors, R36 (100K) and R37 (3.3K). Terry, K9TW, told me those resistors are some times changed to "hot rod" the hybrids. I wasn't aware those resistors were changed to "hot rod" the hybrids so check them.

Also, check the final unit's R7 and R8, both 100 ohms. They are the final unit's "screen resistors". If they both measure within tolerance you do NOT have to replace them!!!!

Let me know what you find when checking R36 and R37 on the RF unit and R7 and R8 on the Final Unit board. Also let me know if you can tune your 830 up to full power into your dummy load.

Peter,

You say that R11 is OPEN. Okay that will result in 210A voltage to be "0VDC" just as I said it would.

I said you should recheck your voltages on the Rectifier Unit's 210A and 210B terminals, it appeared you had them "backwards". Once you found R11 was open, did you recheck the 210A and 210B voltages as I asked you do to? Since you say R11 is "open" then, as I indicated above, the voltage on the Rectifier Unit's "210A" terminal is "0VDC". You initially said the voltage

on the Rectifier Unit's "210B" terminal was "0VDC" which I didn't believe you and so I asked you to recheck your voltages. What is the voltage on the Rectifier Unit's "210B" terminal?

73
Mike W5RKL

On 12/9/2013 7:14 AM, Peter Ravn wrote:

Mike,

Thanks to your patience and conscise instruction I found the culprit: R11 is open. I checked all the other diodes on the rectifier board, including the D6 you mentioned, and they are all ok.

I have a new 470 ohms 1W resistor to replace the bad one, but before doing so I should like to know what made R11 open. What else to check before firing up my TS830S?

Once again thanks for your help. It is outstanding.

Peter,

You measured +263VDC at 210A but zero VDC at 210B? That doesn't make sense. I think you have the voltage measurements at the Rectifier Unit's 210A and 210B "backwards". I think the Rectifier Unit's "210A" terminal voltage is "0VDC" and the Rectifier Unit's "210B" terminal voltage is "+263VDC". You need to "recheck" the voltages on the Rectifier Unit's "210A" and "210B" terminals.

You also did not comment on the condition of "R11" (470 ohm) on the Rectifier Unit I asked you to do. Did you visual inspect R11? Did you measure the resistance of R11? If R11 is "open" then the Rectifier Unit's "210A" terminal voltage will be "0VDC" which will results in 0VDC on the RF Unit plug 9 pin 2 (210A) and 0VDC on SG1, SG2, PD2, and the Final Unit's "SG" terminal and the final tube's screen, pin 3.

Are you using the TS-830 schematic to troubleshoot this problem? You need to do that.

73
Mike W5RKL

On 12/9/2013 1:49 AM, Peter Ravn wrote:

Mike,

There is no voltage on RF unit plug 9 pin2 (210A). On 210A on the rectifier there are 263 DVC, but zero on 210B, so where does that leave us?

Emne: Re: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter,

The Rectifier Unit's HV supply is a "Voltage Doubling" supply. Therefore, you will not see 800VAC on the transformer's "800AC" terminal. I recommend you spend some time studying how voltage doubling supplies work. The ARRL handbook has a section that covers different types of power supplies, including voltage doubling supplies.

Your problem does not appear to be a bias problem but rather a loss of screen voltage to the driver and both final tubes.

Loss of screen voltage to the driver and both final tubes will shut those tubes "down", no conduction in the tubes will occur. That means you will not see any drive from the driver tube to the final amplifier, no final tube IP current indication of any kind in any mode, and the final amplifier's cathode voltage will be zero.

The reason the final tube cathode voltage is zero is simply because there is no current flowing in the final tubes. This is part of vacuum tube theory which is discussed in the ARRL handbook, early editions are the best or you can study the same theory in John T. Fryes, Basic Radio Course which is available in CD form from a seller on eBay.

Since you have already checked the final tube's screens for voltage and found it to be zero, now check the RF Unit plug 9 pin 2 (210A). This is the driver tube's screen voltage from the Rectifier Unit's 210A source. If voltage is zero at RF Unit plug 9 pin 2, is zero check the Rectifier Unit's "210A" and "210B" supply outputs. If voltage at 210A "and" 210B are zero, check Rectifier Unit diode D6, it's most likely "open" resulting in zero voltage at 210A and 210B, hence zero screen voltage to the driver and both final tubes. Visually inspect R11, 470 ohm resistor on the Rectifier Unit. Resistor R11 is physically located on the Rectifier Unit but R11 is connected between the positive terminals of C180 and C181 which are on the IF Unit.

If D6 is open, check C180 and C181, both are 22ufd 350VDC "Radial lead" capacitors on the IF unit, they are the filter capacitors for the Rectifier Unit's 210A and 210B supply, one or both could be shorted which would take out D6 resulting in zero Rectifier Unit 210A and 210B voltage, hence no

screen voltage to the driver and both final tubes.

73
Mike W5RKL

On 12/8/2013 3:59 PM, Peter Ravn wrote:

Mike,

Here is an update on my latest findings.

On the rectifier board there are no voltages on TUNE, SG1, SG2, PD1 and PD2. On AC800 there are only 324 VAC instead of 800 VAC. Voltages on all other terminals on the rectifier board are ok, including the bias voltage which is ☐ 110 DVC. R15 was checked and found ok. The preliminary conclusion is that the finals are getting no screen voltage from the rectifier.

In TUNE/SEND the panel meter shows 900 DVC.

When the HEATER is switched on, the filaments in the finals come alive. Voltages on the filaments are according to specs. There are ☐ 103 DVC on the grids (pins 5), and with the bias potentiometer on the rear the voltages can be adjusted from ☐ 93 to -103 VDC. So this part seems to work . But there are no voltages on the screen or on the cathode. Screen and cathode resistors were checked and found ok, so the problem must be somewhere else.

Good night and good luck.

Peter, OZ8CTH

Peter,

Loss of bias voltage to the final tubes will result in the final tubes conducting to saturation levels even in receive. Loss of bias voltage to the final tubes may have permanently damaged your final tubes.

Have you checked/measured the bias voltage at the Rectifier Unit's "-C" terminal?

I recommend you troubleshoot the bias supply from the Rectifier Unit "-C" to the final tubes to find where the loss of bias voltage is occurring.

Topic: 46257 Message: 46709

Peter:

Here is my unsolicited opinion. It really depends on how risk averse you are. To know that you have to understand the jeopardy. What is the worse thing that could happen?

There probably is not a single one of us who have experienced cathode resistor failure who didnt put in new resistors and try it again with the same tubes and that includes me. Often nothing happened or hours or few days later they popped again.

Only way you could screen the tubes that I know of is with a hi-pot or put them back in RF service in your TS830. People have the same decision to make when a 572B arcs over in their SB-200s or even with higher power finals.

So what is the risk? What can happen if one of these 6146Ws arcs over again?

First a tube arc over is different than thermal runaway. Tube arc over almost always is from anode to cathode as the beam plates are physically closest to the anode. This generally does not cause element melting or sagging to the extent that internal shorts are developed. It usually doesnt vaporize the anode and beam forming plates due to the mass of metal involved. Not a thin grid like structure. Thermal runaway on the other hand produces extreme elevated temperature for much longer time and can cause elements to deform and sag and short and destroy the tube. Probably worse case tube arc over would be from Anode to Control Grid. That is rare in my experience, but causes lots of damage to ALC circuit, bias pot, -C supply, TIF amp, meter FET etc. I would never use those tubes again.

So if you install new cathode resistors and want to try it again with same tubes you may or may not experience another arc over. They may function just fine. However, if you experience another Anode to Cathode arc over what is the jeopardy?

1. Loss of panel meter.
2. Stress on HV filter caps, HV rectifier diodes, and Power Transformer windings.
3. Stress on RF plate choke and small VHF plate choke
4..Popped cathode resistors (chance to lift a foil during repeated replacement)
5. Unanticipated down time

Before I got my DC hi-pot I would no longer use any 6146 final that was involved in a blown cathode meter shunt event. I simply did not trust them. Now that I have a hi-pot I would test and if the tube would hold off 2000 vdc to 2500 vdc then I might use it. If it breaks down at 1500 vdc I would definitely not. Tubes see approx 1600 volts peak voltage swing in service.

Absent a hi-pot my advice is to NOT USE THESE TUBES again in your KW hybrid unless you understand what jeopardy the rig would face with another arc over event and are willing to accept that risk.

I might try them in my HeathKit DX-35 or DX-60 which has lower dc plate voltage and lower peak voltage swing than the KW hybrids.

It appears to me you have four choices:

1. Try the 6146Ws again
2. Try a different set of finals
3. Install the protection mod and use different tubes
4. Install protection mod and try the 6146Ws again

In my case I got tired of repeat blown resistors with different brands of tubes. I have also replaced the panel meter in several customer radios. Fortunately not in my rigs.

I dont know if the protection mod has been called upon to act or not. Since installing in all 4 of my KW hybrids I have not blown any cathode resistors or the primary fuse. It could be the mod has never been challenged? I am running RCA 6146B and JAN Sylvania 6146W tubes. Supposedly NOS.

Just my 2 cents worth.

It was "one of those things." The weak, noisy and distorted audio on my TS-830s cleared up after I re-seated (for the third time) the shielded VCO line cable. Apparently, the shield ground wasn't "making it".

I am somewhat mystified by the cause and effect, but -- nevertheless -- am gratified that all is back to normal.

The original problem remains, however: very low drive and output on 10 meters. Tweaking L21 brings it up a bit (though not to normal levels), but doing so is obviously compensating for an aging or defective component that has knocked the circuit out of resonance.

Any ideas?

Oh -- I must mention the compassion and generosity of one of our group. After I destroyed my original L21 RF coil through overly enthusiastic slug turning, jamming and subsequent destructive attempts to recover, he sent me a replacement. It arrived yesterday and thus began my most recent adventure. I will name not my benefactor to prevent him from receiving a flood of "hey, do you have a spare..." requests, but mention his kindness as a demonstration of the finer aspects of this forum of friends.

Happy New Year, y'all!

Jim,

Well... glad you got it back up an operating...to a point.

Lack of adequate output on 10 meters when the lower bands are ok, may indicate a failing driver tube.

You should be able to get full ALC meter swing on 10 meters. Tune rig for max output, put rig into transmit, watch drive level(ALC) it should be steady...if it falls off...your 12by7a is
going flat. You can also watch the rigs Ip output on the rigs meter...if it falls off...possibly the finals are getting tired too

Thanks Jim and Joe,

The low drive and output on 10 are apparently not products of tired tubes. Both the driver and finals are brand new. They were the first components I changed when the problem became apparent, though the symptoms are just the same as a bad driver (or aged finals) would trigger.

Hmmmm.

Craig,

Are your driver and final tubes KNOWN good? If newly purchased, more than likely they are. If you have just tested them in a "tubes tester" and they tested "OK" or some number indication that they are good...be aware that the testers do not guarantee that the tubes will work in the actual RF environment. Many members keep a set of KNOWN good finals and driver to help eliminate such a problem.

Just another wrench in the works hihi

Terry,

Thank you for listing the pros and cons. The choice is naturally mine, and it is not an easy one. If I order a new set of 6146W's from RF Parts, I may end up with the same problem and lose another 150 dollars. Alternatively I can install the ones that turned RED when all the troubles started a few weeks ago. Or I can install an old set of 6146A/B I have never used before and whose story I do not know. However, the risk of another arc will still be there. That is why your cathode/screen protection modification will be the first thing for me to do.

Emne: RE: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter:

Here is my unsolicited opinion. It really depends on how risk averse you are. To know that you have to understand the jeopardy. What is the worse thing that could happen?

There probably is not a single one of us who have experienced cathode resistor failure who didnt put in new resistors and try it again with the same tubes and that includes me. Often nothing happened or hours or few days later they popped again.

Only way you could screen the tubes that I know of is with a hi-pot or put them back in RF service in your TS830. People have the same decision to make when a 572B arcs over in their SB-200s or even with higher power finals.

So what is the risk? What can happen if one of these 6146Ws arcs over again?

First a tube arc over is different than thermal runaway. Tube arc over almost always is from anode to cathode as the beam plates are physically closest to the anode. This generally does not cause element melting or sagging to the extent that internal shorts are developed. It usually doesnt vaporize the anode and beam forming plates due to the mass of metal involved. Not a thin grid like structure. Thermal runaway on the other hand produces extreme elevated temperature for much longer time and can cause elements to deform and sag and short and destroy the tube. Probably worse case tube arc over would be from Anode to Control Grid. That is rare in my experience, but causes lots of damage to ALC circuit, bias pot, -C supply, TIF amp, meter FET etc. I would never use those tubes again.

So if you install new cathode resistors and want to try it again with same tubes you may or may not experience another arc over. They may function just fine. However, if you experience another Anode to Cathode arc over what is the jeopardy?

1. Loss of panel meter.

2. Stress on HV filter caps, HV rectifier diodes, and Power Transformer windings.

3. Stress on RF plate choke and small VHF plate choke

4..Popped cathode resistors (chance to lift a foil during repeated replacement)

5. Unanticipated down time

Before I got my DC hi-pot I would no longer use any 6146 final that was involved in a blown cathode meter shunt event. I simply did not trust them. Now that I have a hi-pot I would test and if the tube would hold off 2000 vdc to 2500 vdc then I might use it. If it breaks down at 1500 vdc I would definitely not. Tubes see approx 1600 volts peak voltage swing in service.

Absent a hi-pot my advice is to NOT USE THESE TUBES again in your KW hybrid unless you understand what jeopardy the rig would face with another arc over event and are willing to accept that risk.

I might try them in my HeathKit DX-35 or DX-60 which has lower dc plate voltage and lower peak voltage swing than the KW hybrids.

It appears to me you have four choices:

1. Try the 6146Ws again

2. Try a different set of finals

3. Install the protection mod and use different tubes

4. Install protection mod and try the 6146Ws again

In my case I got tired of repeat blown resistors with different brands of tubes. I have also replaced the panel meter in several customer radios. Fortunately not in my rigs.

I dont know if the protection mod has been called upon to act or not. Since installing in all 4 of my KW hybrids I have not blown any cathode resistors or the primary fuse. It could be the mod has never been challenged? I am running RCA 6146B and JAN Sylvania 6146W tubes. Supposedly NOS.

It bemuses me that once the experiential phase of troubleshooting low RF drive and low RF output is over (try new driver tube, try new finals, clean the bandswitch contacts etc) why people do not automatically reach for either an RF millivolt meter or an O-scope and run the TX Level Diagrams that Kenwood was so kind to give us.

If you have neither of those pieces of test gear you will need a VTVM and RF probe. Remember need a multi-diode probe to get on Driver tube plate and 6146 control grids as single germanium diode probe is only good for approx 30 volts.

In about 10 minutes you should be able to at least find where the drive level is down at and can then begin trouble shooting that area. Not likely low TIF signal on 10 meters as TIF if not band specific. So no real reason to be testing 8.830mhz from the IF board. Where then is the next logical place to look?

Well can start at output of TX Mixer and work toward the 6146 control grids or start at the control grids and work way back to TX Mixer.

What is the rf drive level at TX Mixer output at TP-4?

What is the rf drive level at the plate of the Driver tube?

You have two parallel resonant tank circuits that must get switched in and it is sounding like that is not occurring.

Remember the TX Level Diagrams were taken at 14.2mhz so will be approx levels.

At 28.5mhz should see something like the following:

3.0v rms rf volts at TP-4 (approx 8.8v p-p)

54.0v rms rf volts at Plate of Driver tube (approx 153v p-p)

48.0v rms rf volts at 6146 control grids (approx 136v p-p)

Peter:

If the finals turned red it wasnt from an arc over. It was from loss of operating bias. The high plate current caused the anodes to glow red. I would be even more worried about using finals that experienced thermal runaway than I would those that arced over. As I mentioned much more likely to have sagged elements that shorted together and or vaporized during a thermal run away event.

The protection mod will not protect tubes from thermal runaway. I believe Mike W5RKL helped you verify you had a good clean bias voltage pot with no dead spots anywhere in the full range of rotation. I think also verified could set operating bias to approx -60vdc to establish normal 60ma zero signal current. This is a must to prevent a repeat incident.

I am sorry I confused arc over event with thermal runaway. Not sure how that happened. Very seldom will the cathode resistors pop open during a thermal runaway event. Certainly not in time to prevent final tube damage.

We are talking about TS-830S and not a TS520,

I have owned several and currently own two and I have never seen one that would not do 100 watts out on 10 meters. There is a reason why, but too many key strokes to explain here.

Yes pretty common that a TS-520 will have a little less output on 10 meters. 75 to 80 watts is about as good as they will do. The fallacy is that it is normal for a TS-520 to have no ALC indication on 10 meters and that is baloney. Never had one on bench that I could not get ALC indication on 10 meters. Wont be as much as later hybrids and takes pretty much full Car Level, but always able to produce enough drive to overcome the DC bias offset and produce positive grid current and resulting ALC indication.

Having lower output power on 10 meters has nothing to do with 12BY7A or S2001 tube upper frequency limitations or "gold plated wiring or voltages". The tubes are no where near upper frequency limitations or transit time effects. Skin effect is not a factor at 30mhz.

We are all aware of and have come to accept that pretty much all multi-band band switching transmitters, exciters, and linear amplifiers will have lower output power on 10 meters. We accept it and live with it , but few question or understand why. We also know that usually can do better if we design and build a single band transmitter or linear. This has to do with component layout and use of vacuum variables and other tricks.

It is actually pretty easy to understand what is going on with KW hybrid and pretty much same design challenge for Heath and Yaesu and Drake and ....

It is a combination of factors, but mostly due to design trade offs in optimum LC ratios and resonant circuit loaded Q. The large frequency range from 160 meters to 10 meters presents the designers with a challenge. That challenge is due to parasitic capacitance. That capacitance is primarily due to the input and output inter-electrode capacitance of the tubes and the capacitance of the circuit PC traces and bandswitch contacts and lead wires. At 10 meters this fixed parasitic capacitance becomes a significant factor to deal with. Infinite combination of L and C that will resonate at 30 mhz, but not all are efficient and/or practical to build and make adjustable.

This fixed minimum capacitance becomes more of a factor as you go up in frequency because Xc gets smaller. Lower Xc means more feed thru power and more grid losses which means more driving power required. It forces the designers to use tuned circuit inductors (Transmit mixer, Driver tube plate circuit, and Pi-network tank) that are less than optimum value. We would like to use High C parallel resonant circuits where RF energy is not wasted as heat, but this fixed minimum parasitic capacitance prevents that. The dielectric loss of a High Q rf capacitor is typically much lower than the IR copper losses of an inductor. So the designers have to live with less than optimum LC ratios due to having to use a higher L than they would like to use to resonate with this fixed circuit parasitic capacitance. .

If you dont believe this or havent thought about it take a look at the 10 meter Mixer and Drive tuned circuits in your KW hybrid and ask yourself where are the fixed capacitors for these slug tuned coils. There are no fixed capacitors in parallel with these slug tuned coils as there are on the lower bands. The capacitance is in the input and output inter-electrode capacitance of the Driver tube and the associated pc traces and bandswitch contacts. The tube capacitances are actually used to tune these circuits to resonance. Just not at optimum LC ratio and not at optimum loaded Q. This means RF energy is lost in form of heat.

The tank circuit (Pi-network) also presents a problem on 10 meters as designers have to live with the output capacitance that the 6146 final tubes present. This capacitance is in shunt with the tank capacitor which has a pretty high fixed minimum. This fixed minimum capacitance again means using more than optimum inductance on the tank coil tap so that it can be tuned to resonance. More inductance means more RF energy wasted as heat. This is why

we see the small aux coil of heavier gauge for 10 meters.

If you were a designer of a 160 meter to 10 meter multi-band transceiver and could chose between which end of the wide bandwidth range for the least efficiency which would you chose? It is an easy answer. You would chose 10 meters for the lower efficiency end of the operating range as it is the easiest to compensate for this lower efficiency and resulting lower output power with external means.

Isnt it easier to build and swing a high gain directional antenna for 10 meters than it would be for 160 meters. So we live with and expect lower output power on 10 meters and the propagation characteristics and high gain directive antennas more than compensate for it.

More detail to understanding why it is "normal" to see less output power on 10 meters, but too many key strokes.

Less than optimum LC ratios and loaded Q are the the primary factors at play here.

Terry K9TW

Have you checked the SG switch to ensure it is in the ON position? Also, have you measured the final tube screen voltage, pin 3 on the final tube sockets or the SG terminal on the Final Unit PC board. The approximate final tube screen voltage in standby (receive) is +265VDC with the SG switch set to ON but switches to approximately -105VDC with the SG switch set to OFF.

Another subject.
May I also remind you that all members are required to add a "signature" to the end of each message the member posts on the group. That signature can be the member's first name, call sign, or both. "Screen names" such as "gigawatt900" or "lcr800" are not acceptable signatures at the end of a message.

Topic: 46669 Message: 46728

In my closing summation I should have re-stated all of the primary reasons for increased loss at 10 meters. They are in the text but may be too cryptic.

1. Losses in the Mixer and Driver stage tuned circuits due to having to use less than optimum LC ratio and optimum loaded Q. Typically loss is approx 1% to 2% of total RF output power.

2. Losses due to higher drive power requirements due to grid circuit losses. RF current flows thru Cgk (control grid to cathode interelectrode capacitance) and thru Lk (internal cathode lead inductance). A 12BY7A has approx 10 pf of input capacitance and a 6146B has approx 13 pf of input capacitance. For the 12BY7A this means an Xc of approx 8k ohms at 1.9mhz and 520 ohms at 30 mhz. For the 6146B this means an XC of approx 6.4k ohms at 1.9mhz and approx 410 ohms at 30 mhz. This lower resistance at 10 meters means higher RF drive current is fed thru from the control grids to the cathode series inductance and to chassis ground thru the cathode rf bypass caps. Typically loss in RF drive at the finals is 1% to 2% of total RF output power.

3. Pi-network tank circuit losses due to less than ideal LC ratios and less than optimum loaded Q. Results in higher I^R losses. Typically around 3% at 160 meters and approx 6% at 10 meters.

A minimum of 10% total output power loss at 10 meters would not be unusual. In practice depending on which model you own it can be more or less. RF board and band switch layouts are different between the rigs. The tanks are pretty similar in design and physical layout.

I will drop this now. If anyone is interested in talking any aspect of KW hybrid design be glad to do so off the Reflector.

Love to see someone elses calcs for what the 12BY7A sees when it looks at the 6146 control grids. I also have driver stage RF input power calcs, RF output power calcs, and experimental results with terminating the plate circuit with different values of dummy load resistors and how that compared to my Rg calcs.

In fact it actually has more to do with tank circuit design. There are a
few tubes like the TT21 which is getting a little lossy on 30 MHz but
most compact transceivers have BIG compromises in the component values
in the plate circuit of the output tubes. This is usually due to simple
lack of space. The TS820 is actually less than 50 % efficient on several
bands. It is one reason why the 6146B's etc can get stressed more easily.
A quick calculation shows you that at 100 watts output the plate/screen
disappation for the 2 tubes is probably about 70 Watts or more (right
near the top end of their specs) . Old QST figures indicated that on
some bands the TS820 was not able to output
more than about 75/80 watts because of this tube stress problem.
If they were running at 66% this would be reduced to ~40 to 50 and the
anodes would be a lot happier and your rig would run cooler.
I am starting thinking about a major rebuild of my TS820 final using a
single 4CX150 or similar and totally redesigning the tank coils to bring
up the efficiency. This would be possible because of the increased space
available. But this is a long term idea until I get a suitable tube.

I switched from 40 meters to 80 meters and I am getting 100 watts out.
My guess is the band switch needs to be cleaned.
I also need to neutralize the tubes.
Is their a description of how to do this on this web sight?
I have a plastic screwdriver and an o-scope to use for this.
Thanks

Dale,

The TS-830 final amplifier neutralizing procedures are in the TS-830 operator's manual, page 27 paragraph 6.4. It is also part of the alignment procedures in the TS-830 service manual, step 25.

I recommend you thoroughly read and understand the neutralizing steps and have the necessary test equipment on hand first, before you attempt neutralizing the final amplifier.

You really need to have some one look at your TS-820. There is clearly a problem and it doesnt sound like a design problem. Perhaps not well aligned or a problem with low drive on some bands. The 6146 finals are no where near maximum upper frequency limit at 30 mhz. Why you would even mention it is a mystery.

I own a TS-820 and have worked on my share. I have included the loading results from my personal TS-820 that I just ran today on the bench. These output power levels in my experience are typical of a spec TS-820.

If I owned a TS-820 or any hybrid that was 50% efficient on any band I would never accept that this was per design unless perhaps I had soft finals. Physical size and room in the PA cage has nothing to do with it. What would you do to your TS-820 if you had more room? What "bigger" components would you install in the PA cage?

10 meters is a compromise in your TS 820 tank circuit due to the minimum capacitance value of the air variable tank capacitor that is in shunt with the output capacitance of the 6146 tubes. That tube output capacitance is what a KW engineer has to design around. All you can do there is make sure you have short anode and plate blocking capacitor leads and a high quality tank cap with as low a minimum capacitance as you can find. KW has done that with the close component spacing that you bemoan.

In order to have some tuning range to dip the tank to resonance on 10 meters the design engineers had to use a value of inductance that is much higher than they would have liked to. They are using a compromise LC ratio which is less than optimum which results in less than optimum loaded Q. This means higher I ^ R losses ie heat from the circ current flowing thru the higher resistance that this higher inductance presents.

Nothing at all to do with how big something is in the tank. If we had lone skinny runs of wire then we could say shame on KW but that is not the case.

At 28.5mhz have you measured the tank capacitor value and tank inductor value at resonance? What is the LC ratio? What is the Q?

Have you made the same measurements on 160 meters or 80 meters and compared the results?

I am interested in comparing results.

If you own service manual suggest you run TX Level Diagram on all bands. Clearly a problem if you are seeing 50% efficiency on some bands.

Here are my loading results into 50 ohm dummy load that I ran for this response to you.

1. 1.9 mhz @200ma = 90 watts @225ma = 105 watts
2. 3.8 mhz @200ma = 90 watts @225ma = 105 watts
3. 7.2 mhz @200ma = 90 watts @225ma = 105 watts
4. 14.2mhz @200ma = 85 watts @225ma = 95 watts
5. 21.2mhz @200ma = 85 watts @225ma = 90 watts
6. 28.5mhz @200ma = 80 watts @225ma = 85 watts

Lowest Plate voltage = approx 820vdc

Maximum CAR pot level = 3

Pair of 6146W JAN Sylvania finals with very few hours on them.

Remember the TS-820 is rated by KW at 160 watts dc input power and not 180 watts DC input like the TS530 and TS830. It has nothing to do with the tubes dissipation ratings as they all use the same tubes. It has nothing to do with how big or how much room is in the PA cage. My guess is it has to do with the VA rating of the power transformer, but no documentation that I know of to prove that.

Loading your TS-820 to 225ma is not placing undue stress on the final tubes or shortening the life especially in ICAS duty cycle modes.

46733. Kenwood Hybrid Net Update (December 29, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-12-29 23:17:05 UTC
From: Mark Gilger
Topic: 46733 Message: 46733

Net Info:
Saturday: 7.235 @ 3:30pm Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Web Site:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

The net recently celebrated it□s 2nd year in existence on November 1st, 2013. The yearly check-in totals are posted at the bottom of this message. It showed we had a 10% increase in our Saturday check-ins and an 8% on Sunday as compared to the 2012 check-ins.

Jimmy, WB2KNR ran the Saturday net on 40 meters. He had 22 check ins under poor band condition. We had the following number of radios checking in.

3 running TS-520(x)
1 running TS-530(x)
1 running TS-820(x)
6 running TS-830S

Jimmy was using his TS-520.

The Sunday□s 20 meter net had 32 stations checking in under good band conditions. There were 13 new stations checking in, W6DSL, K6TWT, AB1KC, N4JK, W0TAS, W5DUG, N0VQ, WA7AFL, KE7HLK, KL7IBY, KF6YIJ, VA7GCD, and N0GKO.

Out of those, there was:

4 running TS-520(x)
0 running TS-530(x)
2 running TS-820(x)
5 running TS-830S

I was running my 820 twins, TS-820s + R-820.

We have been having several people checking in regularly with their TS-430, TS-440, and TS-940□s, which of course is not a hybrid, although over 30+ years old. Everyone is welcome as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a net control station, please send me an email. Currently it's just myself, WB2KNR and WB0SGA. I would like to get several more. If we do, we can alternate so everyone might be on a 3-4 week rotation. It's a lot of fun and a good way to make sure you station is optimized.

For anyone that has not heard, we have a new web site that WB4HFN is hosting. He currently has a very nice site for Drake, Collins and Heathkit and now Kenwood Hybrids. Good quality manuals plus sale flyers and brochures will be found here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins
Nov. 2012 - Oct. 2013 Saturdays total 828 check-ins, Sunday total 609 check-ins

November 2013, Saturday☐s net total = 94, Sunday☐s total = 85
December 2013, Saturday☐s net total = 87, Sunday☐s total = 103 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

I started the process to neutralize the tubes.
The first thing the manual states is tune into a dummy load at 28.5 MHz.
As soon as I hit transmit in the tune position the main fuse blew.
Earlier this morning I used the radio to talk to the people on the breakfast club on 3.73 MHz and they said the radio sounded real good so apparently it worked all right on the lower frequency.
Another thing when in the tune position the radio only gets about 2 to 5 watts output but when I transmit in short wave it puts out 100 watts.
When the fuse blew would it be from runaway oscillation of the tubes?
Would this rune the tubes?
Would it help to neutralize the tubes on a lower frequency and work my way to 28.5 MHz in steps?
Thanks for any help.

Topic: 46619 Message: 46739

Craig:

Sounds like you have lost AGC bus voltage. This dc control voltage is applied to Gate 2 of the IF and RF gain controlled devices and absent this voltage will have no Rx and S-meter will peg as it is a voltmeter measuring the AGC bus. It is reverse reading voltmeter. With +3.6vdc on the bus the S-meter will read Zero. As the voltage goes down (due to reducing the rf gain pot or from strong off air signal biasing on AGC detector) the meter will move off Zero and go up scale. The lower the voltage on the AGC bus the higher your S-meter (voltmeter) will read and the lower the RF and IF stage gain.

Anytime S-meter pegs and no Rx it means that the AGC bus voltage is no longer at RF-1 level (approx 3.6vdc). One way that can occur is to turn the RF gain pot full CCW. If RF gain pot is not full CCW and S-meter is pegged check this:

1. Measure RF-1 at Audio board Conn 9. Should be approx 3.6vdc. If not there then measure regulated 9vdc at TP-6. Need 9vdc regulated to produce RF-1. If good RF-1 at AF board move on to IF board.
2. Measure RF-1 at IF board Conn 8
3. If you have good RF-1 at IF board Conn 8 should have an energized AGC bus assuming dont have a dirty molex connector pins or bad solder joint.

If you have a 10meg to 11meg DMM or VTVM can measure AGC bus voltage, but meter will pull it down. You wont be able to measure it accurately but can tell if it has positive voltage on it. 3.6vdc will be pulled down to approx 3.0vdc or less. Measure at Conn 15 pin 3 and make sure you are on Pin 3 and not Pin 1 as it has SG voltage on it.

If you have a dc bench supply can apply 3vdc at Conn 15 Pin 3 and see if Rx comes alive and S-meter comes off the peg. If no bench supply just use couple of flashlite batteries in series. Apply negative from battery to chassis ground and connect positive down inside Pin 3. You are just paralleling a low impedance power supply with a high impedance power supply. If Rx comes alive, but S-meter stays pegs then you have lost meter JFET Q11 (it is shorted)
.

Emne: RE: SV: SV: SV: SV: SV: SV: [TS-520_820_530_830] TS830S no bias

Peter:

If the finals turned red it wasnt from an arc over. It was from loss of operating bias. The high plate current caused the anodes to glow red. I would be even more worried about using finals that experienced thermal runaway than I would those that arced over. As I mentioned much more likely to have sagged elements that shorted together and or vaporized during a thermal run away event.

The protection mod will not protect tubes from thermal runaway. I believe Mike W5RKL helped you verify you had a good clean bias voltage pot with no dead spots anywhere in the full range of rotation. I think also verified could set operating bias to approx -60vdc to establish normal 60ma zero signal current. This is a must to prevent a repeat incident.

I am sorry I confused arc over event with thermal runaway. Not sure how that happened. Very seldom will the cathode resistors pop open during a thermal runaway event. Certainly not in time to prevent final tube damage.

Terry K9TW

Topic: 46257 Message: 46741

Peter:

C8 is an RF bypass capacitor. Its performance or failure would not be related to tube arc over or tube thermal run away events.

It is extremely difficult to make a solenoid wound Plate choke that will present an acceptably high amount of inductive reactance across the frequency range of our KW hybrids without having a series resonant hole in it close to one of our bands. Adding 160 meters to the transceivers made it even harder to design an effective choke. Couple of options. 1. Use space wound choke to break up the distributed capacitance or 2. Add an additional choke at cold end and orient it at a right angle to break up the mutual inductance coupling. KW chose method 2 as space winding means a much taller choke.

L2 Plate Choke is there to allow us to supply 900vdc anode voltage to the 6146 finals and prevent RF current from flowing back to the HV power supply. The HV filter caps wont like RF. In addition to not wanting ripple on our DC supply it will cause dielectric heating and over time can damage the HV filter capacitors.

L2 is approx 168uhy with a parallel resonant point at approx 14.0 mhz. This means it will have the highest inductive reactance around 20 meters ie it will function best there to provide the highest inductive reactance (opposition to rf current flow). Its first series resonant hole is around 25mhz which is almost too close to comfort for 24mhz operation as that means it will have the lowest inductive reactance and less opposition to RF current flow.

Since L2 cannot offer high reactance across the entire operating range there will always be some RF current that will get past it. We place C8 at "cold end" of the choke to shunt any RF that makes it past L2s windings to ground. C8 has to be a Type 1 capacitor designed for RF current. It is essentially in severe duty.

It is not uncommon to see it discolored, have hole blown in it, and/or the case split open. Always good to inspect it when working on PA cage and as you discovered measuring the capacitance is not an effective way to assess its condition.

Having not witnessed your event and only going on my understanding of what you described it clearly sounds like thermal runaway due to loss of -dc operating bias voltage which is not related to the damage you see on C8.

Who knows maybe you had thermal runaway accompanied by an arc over? If elements sagged could have actually contacted and shorted as opposed to anode voltage ionizing the gas and conducting to the beam plates in the typical manner.

Terry K9TW

Terry:

Got it! Following your expert and -- as usual -- highly detailed "cause and effect" narrative, I applied my trusty ME-260/U multimeter with RF probe to the job. The very first suggested measurement indicated no voltage present on the AF board connector #9 RF-1 pin -- that is, until I nudged the connector with a bit of authority.

Bingo! Reception returned and the S-meter fell to normal readings. Subsequent, highly magnified inspection of that pin and its next door neighbor revealed barely discernible cracks in their foils that had been quite possibly exacerbated by my Molex connector unplugging, cleaning and re-seating regimen a day earlier. As many others, yourself included, have mentioned frequently, these radios' aged circuit boards are quite fragile.

I, again, commend and thank you for generously sharing your time and expertise, Terry.

Incidentally, my short experience with these Kenwood hybrids is modifying my habits for the better. I do not have a technical education (well, in electronics, that is -- I'm an old Naval Aviator with a considerable background in aeronautical disciplines). All things ham radio have been self taught during relatively short, "leisure time" hours. I have some experience in homebrewing, a great deal of experience in kit building and long experience in restoring vintage equipment employing point-to-point wiring, so my operational skills are good and my wiring and soldering neat, clean, orderly and efficient.

Accordingly, I have often favored the "shotgun" approach to reviving old radios, beginning with wholesale recapping followed by the replacement of other components as deemed appropriate. I can see now that such methods with these radios and similar devices with aging circuit boards and dense component populations is not always wise and that the "if it ain't broke, don't fix it" philosophy is often best employed.

That is one of the many lessons I have learned during my few months as a member of this group.

Thank you, 73 and Happy New Year to all (and special thanks again, Terry).

Craig

Craig:

OK but remember RF-1 is dc voltage and not RF voltage so you cannot measure it with a RF Probe. Just use DMM or VTVM to measure RF-1. RF in this case stands for "Reference" voltage and not Radio Frequency. Some call it the "FET BIAS" voltage and that is not correct.

All the gain controlled devices are dual gate mosfets. They do use dc bias voltage to set the operating point, but that low level dc voltage is supplied to Gate 1. RF-1 is the base or reference voltage for the AGC bus and ALC bus fed thru a 2.2 meg resistor making these busses high impedance power supplies. These busses then become variable dc control or servo voltage applied to Gate 2 and controls the gain of the device. Around 4vdc on Gate 2 produces max gain.

Yes need to be very careful with any and all of the molex connectors and when de-soldering and re-soldering on these old boards. Not the nice G10 and heavy plated boards we have today. Just phenolic boards from the period.

Everyone has different opinions about cleaning all as first step or as regular and routine step. I dont subscribe to that approach after having seen what can happen. Of course comes time when may have to pull and clean, but have to be damn careful and anytime necessary to pull a board it is mandatory to inspect all molex pins under magnification and you simply cannot re-solder them as the pins appear to have never wetted and will not take solder via reheating. Have to clean the oxide off the pins either thru lite sanding, scraping with Xacto knife, or cleaning with an abrasive of some type. Some report good results using an eraser, but that has not been my experience. IF board is probably the most susceptable as it sees the most cycling of connectors with all the in and out installation of various optional filters over rigs life.

Wishing you a Happy, Prosperous, and most of all Healthy 2014
Terry K9TW

46745. Low power output in tune mode TS-830

Dale,

Power output in "tune mode" is always lower, but in this case I suspect that resistors 15 & 16 on the rectifier board...are way out of spec. These two R's cut down power(voltage) to the final amplifier tubes in "tune" mode so they do not operate at full voltage or power..while out of resonance. These resistors are both 56K ohms...and tend to be a common problem with the
"no/low output in tune" complaint. You can go into the "files section" and search "conversations" regarding this topic....probably 2-3 hundred posts. You can check the voltage at the "tune" post on the rectifier board...should be 2-3hundred volts DC...I may be off...by a bit...but anything way lower indicates a possible problem with R's 15 & 16 on the rectifier board

Tnx agn, Terry.

I misspoke. I do have an RF probe for my old military VTVM, but didn't employ it for the DC voltage reading(s).

After determining that to pins on the AF board's connector #9 were less than secure, I very carefully scraped away a little of the green solder resist from the traces involved and resoldered the pins and adjacent lands with my Antex miniature iron. All is well again and the receiver audio sounds cleaner than ever. (This could be my imagination, but I'll run with it anyway).

Back in the '70's, I worked for The Heath Company in the marketing department. But, probably because I was considered an "average" non-techie ham, I was given the happy duty of test building new kits in the amateur radio product line. Among them was the solid state SB-104 and SB-104A transceivers and "peripherals." These marvelous kits employed glass boards and very durable copper plating. This excellent practice was actually an economy move -- or turned out to be -- despite the extra materials cost. More rugged boards, able to withstand the soldering/desoldering/resoldering cycles often meted out by hasty kit builders, meant fewer parts exchanges and reworking by our techs. At Kenwood, the engineers and bean counters probably never figured on a group pf "devotees" like us attempting to keep these wonderful radios spewing RF thirty or forty years on.

All the very best to you, too, Terry.

73 to all,

Craig

I am using a Hewlett-Packard 3466A DVM to measure all voltages.

3.3 volts is now on the RF-1 rail and after fixing the FIX/VOX board, the relays now work. The meter tracks the RF gain control. The high 12 volts on the RF-1 line was caused by a tiny flake of metal finding it way and becoming wedged between pins 4 and 5 on relay board connector RL-1, circuit board side.

The VCO seems to be working. Measured 3.3 volts at TP-4 to ground on all bands. The main VFO is working too. Still no receive yet but things are improving. What's wrong with this TS-820 ?? What do you have ??

It crops up from time to time, but it probably bears repeating - high value resistors subjected to high voltages seem to want to wander off upwards in value. When you find some oddity in an HT circuit, cast a suspicious eye over anything above about 100k first, and then see where you get?

Remember when TVs had CRTs, and not only that but valves? Where I grew up, it was a very "fringe" reception area and the vast majority of "first TVs" people bought were based on the BRC 1400 chassis - VHF/UHF dual-standard, all-valve except the UHF tuner, and by the late 80s when they had filtered down from being the TV in the living room to the TV in the parent's bedroom (after being replaced by a Philips G8) to the TV in the teenagers bedroom (after the G8 was replaced by a Ferguson TX, and the G8 shunted upstairs) then they were showing their age a little and flyback lines were starting to show due to the uncontrollably high brightness. Now, there was this little 220k resistor that went off towards 1M, dead easy to change *if* you knew what you were looking for.

Those 220k resistors and a stock of ZX Spectrum keyboard membranes kept the cash coming in through high-school and I wish I still had my old 1400-chassis set...

Well Craig, the most likely cause I can think of is mistracking of the driver and TX mixer tuned circuits. Are you sure that the coils aren't off tune?
It is, just as you describe, more critical on the lower bands.
So basically do an alignment of the small coils in the TX on the low bands to ensure that the resonances aren't off. I think that it is all in the manual.

Jim

Not sure who you are talking to?

OK to measure DC voltage at TP-4, but really need to ensure you have VCO signal at the RF board where the RX and TX Mixers like to use it as the LO.

You should see approx 1.0 rms rf volts for good Mixer operation. (800mv to 1000mv is typical)

The TP is near T2 just down from RF-1 Conn and just below the tank capacitor drive shaft.

Jim:

I forgot to ask do you have a decent RF Sig Gen?

If so about time to do some signal injection and signal tracing if you have good AVR dc voltages and good AGC bus voltage a the IF and RF boards.

I like to split the receiver in half by applying 8.830,mhz to the RIF terminal on the RF board. Use approx 50mv or -13dBm at Conn RF-1 Pin 1 should give you nice tone and approx 20 over on S-meter. Couple the signal from hot lead of your Sig gen thru a .01uf blocking cap (value not critical).

If you dont have calibrated output just start high and back it down. Some of the LC type generators will just have Hi-Med-Low and a pot. Start on high with pot to max output. Not too critical for the RIF test but for front end work use as low as you can.

This RIF test tells you that the IF amps, AGC detector, Product detector, and Audio stages are all working and the problem then has to be in the Front end.

Can then start injecting at SO-239 and work toward RIF. I usually do this at 14.2mhz and start with around 50uv or -73dBm signal level.

Terry,

I do have a good signal generator. A Hewlett-Packard 8656B. So, I'll do what you suggest start injecting signals and see where they go in the signal chain and where they stop. I'll keep ya posted. So far, this has been a very interesting project. One of these days, I'm going to have to get my hands on a good sweep generator. My main interest in Ham Radio is getting older gear with issues back on the air. All the equipment in my station are rigs that didn't work when I got them. TS-930S, TS-440SAT, 599D "Twins", HW-101, IC-251A, 75A2, Heath TX-1 and now the 820.

Hello again group. Tom in Reno here, W7OA. I sent this post several days ago but I haven't seen it show up yet so maybe it didn't go through for some reason. If it shows up again later, my apologies.
I picked up a TS-520S from ebay - sold as DOA for parts so no ebay story here. Anyway transmit was fine, receive was dead. Traced the problem to the 3rd. IF on the IF board. Q4 was bad - replaced it. Still dead. Came to find T6 IF transformer is open on the secondary. Does anyone have a parts IF board that they would possibly be willing to remove T6 from, or a whole board if the price isn't too steep?

The TS-820 is now receiving signals !! Getting some stations on 20-meters. Found two bad MOSFETS in the IF section. The display is still goofy. Reads 1 .444.4. Interesting. With the screen switch off, going to transmit and back to receive, receive gain is lower. Power cycling brings receiver gain back.

I'm sure after all this messing around, this rig is going to need a complete alignment. At least it's coming back from the dead.

Jim,

You referred to the "screen switch" which I assume you are referring to the rear panel's "SG" switch. The SG switch has nothing to do with receiver gain.

The sole purpose of the SG switch is to control the final amplifier's "Positive" or "Negative" screen voltage. Placing the SG switch to the "OFF" position applies a "Negative" voltage to the final tube screens. Placing the SG switch to the "ON" position applies a "Positive" voltage to the final tube screens. That's all the SG Switch does, nothing more.
